NOTES OF THE WEEK

[JANUARY 7, 1922.]

WITH lengthening day and strengthening sunlight, life will now, should open weather prevail, become more and more noticeable in the garden. The Snowdrop will expand its pen-like buds, only to give place to the gaudier Crocus. The winter-flowering Heaths, the earliest tufted Saxifrages and the tiny *Iris reticulata* all give evidence of growth and progress, as do several species of *Daphne*, including the always welcome *Mezereon*.

The cold greenhouse and its furnishing is to-day a matter of real importance. There are literally thousands of gardens in which the alternative lies between utilising existing structures as cold (or practically cold) houses and demolishing them. In summer such houses can profitably be devoted to Tomatoes or other food crops. Even Cucumbers can be managed. When flowers are really plentiful outdoors many people would gladly dispense with them under glass. The production of flowers in a cold house in winter and early spring can only be achieved by the cultivation of alpinas, which can afterwards be stood outdoors or relegated to the shelter of cold frames. The article on alpinas under glass, which commences in this issue, gives a selection of varieties suitable for the purpose and particulars of their culture.

The Seed Order.—The time has come when the seed order for the coming year urgently calls for attention. The question of perennial seeds was referred to at some length in our issue of December 24th last. It may not be inopportune now to devote a little space to consideration of some less usual aspects of the seed order. First as to vegetable seeds, the ordering of Pea seeds need not detain us, but when one comes to the many varieties of Bean it is well to consider whether one cannot find space under glass, even in a cold house, for early French Beans. Where heat can be given, there are many excellent forcing kinds, but for the cold house there is still nothing better than the old Canadian Wonder. It is well to bear in mind too that any overplus of French Beans may be gathered when half-ripe—they are then called *Flageolets*—and cooked similarly to green Peas. The Runner Bean can often be put to double profit, being

used to form an effective and beautiful screen as well as for its more obvious purpose. Where this is in contemplation, one of the strains of Painted Lady type should be ordered, as these are very prolific, more effective even than the scarlet-flowered and infinitely more beautiful than the white-flowered forms. When ordering seeds of Beetroot, some good Globe variety will naturally be included, owing to the early maturity of this type. Unless wanted for exhibition purposes, it would be wise to discard the old-fashioned long Beets, which are troublesome to lift, in favour of the newer intermediate type which, like the Mangel, grows half in the ground, half out. Sufficient attention is assuredly not given to those excellent winter vegetables, the Sprouting Broccoli. Two or three varieties for a succession should certainly be included in the seed order. Seed should be procured of a good, quick-hearting Drumhead Cabbage for spring sowing and late summer and autumn cutting. With Carrots, as with Beetroot, the man (or woman) who gardens for table rather than for exhibition would be wise to grow only the stump-rooted type. If one likes pink Celery, one should bear in mind that the white matures earlier. To those who prefer the white, on the other hand, it is necessary to point out that the pink keeps better. Those who have almost decided to abandon the culture of Cucumbers owing to the ravages of spot disease should give a trial to that excellent immune variety, Butcher's

Disease-Resisting. The past droughty season so bad for Turnips, served to emphasise the value of the still neglected Kohl Rabi, which should be included in every seed order. The exhibition table has not tended to the production of useful Leeks for the dinner table. It would puzzle any cook to know how to serve 2ft. long specimens otherwise than in soup. For culinary purposes, then, order seeds of one of the compact growing sorts. Do not forget a few bricks of Mushroom spawn; there is no mystery or difficulty about Mushroom culture. Except for exhibition, there is no profit in "Super-Onions." A good crop of James's Long Keeping or Bedfordshire Champion is far more profitable. It should be borne in mind that fern-leaved Parsley is useless except for garnishing. It is very doubtful, even for that purpose, whether it is as suitable as a good curled kind, which should certainly be included in the seed order. Do not forget to include seed of Garden Swedes, which are valuable when cooked like Turnips, and even more valuable for their bleached spouts, which, from a dietetic point of view, contain most valuable salts.

Flower Seeds.—Turning now to the flower seed order, it would be impossible to over-emphasise the value of the *Antirrhinum* for hedging. Tall, semi-tall and Tom Thumb strains are all invaluable, and all are procurable in so many shades that colour harmony can readily be achieved. As regards *Begonias*, few readers will this year succeed in obtaining the new *Narcissiflora* strain, but those in search of novelty may, with confidence, try Sutton's Duplex strain, which has two or three rows of crimped petals forming a very chaste and beautiful flower. The experimentalist may obtain considerable joy by raising Dahlias or *Chrysanthemums* from seed. Really excellent single Dahlia and *Chrysanthemums* may be obtained by this means. Every gardener should each year raise a supply of *Campanula pyramidalis*, a beautiful plant either in pot or border. Few plants are so useful for stopping the inevitable but ugly gaps in the herbaceous border. Many people who, years ago, tried the feathery-leaved *Cosmos* gave it up in disgust because frost so soon cut short its beauty. The early-flowering strains now on hand, however, overcome this defect.

WELCOMING THE NEW YEAR.

THE ALPINE HOUSE

There are to-day in Britain many thousands of greenhouses which, owing to heavy taxation and the cost of fuel and labour, have to be maintained, if maintained at all, without fire heat. Follows a suggestion for their effective use.

AN unheated greenhouse is by many considered a "white elephant." It need not be so. It can be utilised in a variety of ways, but in none more charmingly than as an alpine house in winter. The elaborate alpine houses sometimes seen, with stone pillars to support the staging and "rusticated" back walls "decorated" with virgin cork, are an abomination. There is however, no need for such pretentious fancies. Pots and pans of alpines may be disposed on an ordinary staging just as other ornamental plants are staged. They will not, of course, have the tropic grandeur or oriental fragrance of many orthodox stove or greenhouse plants. They will, however, possess a simple beauty of form and colouring and a perfection of detail worthy of the closest study. They will flower when blossom outdoors is scarce or non-existent and their blossoms will be cleaner than those which, later on, will adorn the rock garden. Some of the more minute treasures, too, will be more fully seen and far better appreciated when thus brought closer to eye level.

It is, of course, possible to grow all rock plants under glass, but most people will prefer to keep the stronger growing sorts for the rock garden, reserving stage-room for plants which, if not difficult, are choice and which will repay study at close quarters. Many hoary plants, such as the *Enerusted* and *Kabschia Saxifragas* and many others with downy foliage, such, for instance, as numerous *Androsaces*, not only withstand our winters better protected from fog, mist and rain but present a much better appearance when given protection.

All alpines, if the necessary plants are available look better in colonies rather than as individuals so that 6 in., 8 in. and 10 in. round seed pans and also the large square propagating pans should be made use of. These last can be massed together to make larger patches of colour if and when desired.

The following are some of the plants which personal taste would select for the alpine house: *Saxifraga longifolia*, *S. Cotyledon* and *S. kolentiana major*, all "Encrusteds," with fine rosettes; *Saxifraga Grisebachii* and *S. Strilnnyi*, the rather difficult red-flowered "Encrusteds," and *S. mutata*, with cool green rosettes and yellowish orange spikes of bloom—a singular lime-hating plant. Of the smaller "Encrusteds," which are really varieties of *S. aizoon*, *rosea*, *lutea*, *paradoxa minor* and *balearica* are excellent, if very "easy" plants, while *Saxifraga lingulata lautoseana* should certainly find a place, as should two or three forms of *S. cochlearis*, and the tiny but beautiful *S. rocheliana*. Coming now to the *Kabschia* section, we have a wide field to select from and the following are only put forward tentatively. A large selection should certainly be grown, which might include *S. Burseriana*, *S. B. major* and *S. B. Gloria*, all very distinct; *S. apiculata*, *S. a. alba*, *S. Boydii alba*, *S. Cherry Trees*, *S. Faldonside*, *S. Petraschii* and *S. I. G. Godsetti*. Of *S. oppositifolia* and its allies the best forms should be selected. These are *S. o. corcina*, *S. o. splendens*, *S. o. alba*, which Farrer ill advisedly called a duty white (there are, however, strains and strains of this plant), and *S. retusa*. For the sake of contrast and to give broad effects, some of the "mealy" *Saxifragas* may

be tried, but they are rather coarse for the purpose and always look rather "washed-out" under glass.

Very interesting and beautiful are the numerous forms of *Androsace* which all flourish exceedingly in pans. Some of the more indispensable are *A. sarmentosa*, with pink primula-like flowers and woolly rosettes 2 ins. or so across; *A. primuloides* which is similar, but smaller and very beautiful, and *A. Chumbyi*, which in many ways resembles *A. primuloides*, but is, in fact, a hybrid between *A. sarmentosa* and *A. villosa*. Other rare and beautiful plants are the mauve-flowered *A. semperivoides* and the yet more uncommon *A. longifolia*.

Androsaces, until the petals are rose and the darker eye almost blood crimson in colour. This is a plant of the widest possible distribution and it is accordingly found in many distinct forms, one of which—*carinata*—comes from the New World. All are worthy of cultivation, but the only other form calling for special mention is *capitata*, which, without being gross, is larger in flower than the typical plant. The rosettes are almost globular and the flowers hugged snugly close to the plants. Much larger than *Chamaejasme*, and singular in the irregular arrangement of the flower heads, is *A. lactea*, with milk-white flowers which do not change colour. *A. foliosa*, so often offered in catalogues, usually

THE BEAUTIFUL KABSCHIA SAXIFRAGE "FALDONSIDE."

The above are all stoloniferous, as is the smaller glossy leaved *villosa*, with white flowers, of which there are many varieties, notably *arachnoidea*. Smaller still, but wonderfully beautiful, with its minute woolly rosettes, is the limestone-loving *A. helvetica*.

Entirely different in type are the peat-loving *Chamaejasme* section, of which the best known are the forms of *A. carnea*, than a well flowered specimen of which nothing more beautiful could be conceived. Desirable forms (in addition to the type) are called *brigitiaea*, *eximea* and *Laggi*, of which the last has a beautiful glowing colour, found in no other of the sub-species. Though perfectly easy to grow and flower outdoors in a peaty moraine, they repay close examination so well that they deserve a place of honour in the alpine house. *A. Chamaejasme*, though less widely known than *A. carnea* and very distinct in appearance, yet belongs to the same section and is very beautiful. The blossoms which open a creamy white with a yellow eye darken, in the way so usual with

proves to be either *A. strigilosa*, or even sometimes *A. sarmentosa*. The true plant of this largest of *Androsaces* has smooth leaves with a fringe of hairs only. It is stoloniferous, but the leaf cluster is too irregular to be worth calling a rosette.

Other beautiful species, mostly limestone-loving and belonging to the *Aretia* class, which all carry their flowers on single stems (not in trusses), are *Charpentieri*, *ciliata*, *cylindrica*—curious in its habit of growth—*pubescens* and *hirtella*. The more rampant *A. lanuginosa*, with silvery trails of foliage and *sarmentosa*-like heads of bloom, is too strong growing for, at any rate, the small alpine house. It is very beautiful, none the less; so is the paler form, *A. l. Leichtlini*.

Of the *Lithospermums* the most beautiful of all, *L. rosmarinifolium*, is suitable only for the alpine house, as it is rather tender outdoors. The little rosemary-like bushes bear their azure flowers in mid-winter. This is more lovely even than *L. prostratum*, and owing to its neat, compact habit

much more suitable for culture under glass. *L. graminifolium*, with its grass-like leaves and azure-tubes, the much smaller *petraea* (*Moltkia petraea*) and the intermediate forms called respectively *L. intermedium* and *L. × Fröbeli*, should also be included as should the widely different *L. canescens*, which is not difficult in strong peat under glass. Its flowers are bright orange yellow.

From the *Lithospermums* it is but a little step to the *Onosmas*, which, with their usually woolly foliage and characteristic bells, are very charming. There are a great number of known species, but most of them are anything but easy to procure. Those best known are *O. tauricum*, *O. stellulatum* and *O. albo-roseum*. The two first have golden-yellow flowers and are very similar in general appearance. Indeed, they are often confused in nurseries. *O. albo-roseum* has broader, woollier (so much whiter) leaves arranged, like those of *tauricum*, in rosettes and flowers which, opening white, rapidly become rose, so that the trusses have a distinct but not displeasing parti-coloured appearance. *O. echioides*, which is sometimes found in catalogues, is not greatly different from *O. tauricum* or *O. stellulatum*. *O. albo-roseum* is a pronouncedly lime-loving plant.

Many plants of special value for the alpine house are included in the genus *Primula*. *Primula Winteri*, for instance, is really only suitable for culture under glass. The same may be said of *Primula floribunda*, *P. × kewensis* and the newer *P. malacoides*. Where space permits such species as *pulverulenta*, *Cockburniana*, and their numerous hybrids, *Beesiana*, *Bulleyana*, *Poissoni*, *Parryi*, *sikkimensis*, and even *japonica*, may be given house room. This, indeed is very desirable if hybridisation is in contemplation. *P. involucreta*, *P. Veitchii* (not too hardy), and some of the better forms of *P. Sieboldi* will probably be included in any case. Very similar to *P. Veitchii* is *P. cortusoides lichiangensis* (the *Sieboldi* varieties are to be pedantic, forms of *cortusoides*). *P. c. lichiangensis* differs only from the perhaps better known *P. Veitchii* in the rather more richly coloured blossoms, the dark brown

BEAUTIFUL IN LEAF AND FLOWER, PRIMULA MARGINATA.

calyces—those of *Veitchii* are green—and in the sturdier, more erect habit and stouter, crisper foliage.

Unless one can afford it the shelter of a greenhouse the rare *Primula Giraldiana* (*muscaroides*) is very difficult to keep. Under glass it is relatively easy. *Muscaroides* is a particularly happy name for this quaint but pretty plant—it is a pity it happens to be an incorrect one. The beautiful violet-purple of *Giraldiana* calls at once to mind the beautiful globular-headed *P. Mooreana*, which is the best of the many forms met with in gardens as *P. capitata*, which is, in fact, a "miffy" plant rarely met with. Somewhat similar but less noteworthy is *P. crispa*. We have now insensibly reached the many forms, varieties and hybrids of *Primula denticulata*. These are all robust growers, but valuable none the less for the alpine house. It is good to raise these from seed and select and re-select the best forms. Seed is often listed as *P. cashmiriana*.

Primula Listeri and the somewhat similar *sinolisteri* are both alpine house plants and remind

one much of *Primula obtusica*. If the same deep rose and ruby colourings can be obtained in these as in *P. obtusica*, that beautiful but venomous plant will soon become a "back number."

P. Littoniana should really have been thought of when discussing *P. Giraldiana*. It has the same curious orchis-like appearance and is most conspicuous on account of the brilliant scarlet bracts which enfold the unopened blossoms. The flowers vary very considerably in colour. Those of violet hue are, of course, to be preferred.

Remembering how keen alpine growers strive to persuade *P. farinosa* to flourish outdoors, it is permissible to suppose that it will be welcome under glass. Compared with the stronger growing and infinitely easier *P. freudosa* it is, however, a poor thing, nor does it compare favourably with the very distinct, long tubed *P. longiflora*, which also is not difficult.

Those who like curiosities will no doubt admire *P. pycnoloba*, which, like *Littoniana*, admirably disguises its race by bearing heads of flower which remind one of some of the congested headed *Campanulas*. It needs similar treatment to the forms of *P. Sieboldi*, to which it is related. Those who have seen that "miffy" treasure *P. Reidii* will want to try it, but it is assuredly far from easy. Like many others, it requires abundance of water (best applied by standing the pans in water) in summer and very little in winter. The late Reginald Farrer, with his natural tendency to the picturesque in language, described it as "hard to keep as love," and "even in nature as rare as perfection." There are numbers of other rare or beautiful *Primulas* which might well be given a trial, but we must conclude by considering only a few of the *Auricula* section. The typical *P. auricula* has yellow flowers and mealy flower stems. It is easy to grow indoors or out and has many forms in its native habitat. Besides such cross-bred forms as Mrs. J. H. Wilson and The General, which are often catalogued as varieties of one species or another, the most interesting alpine *Auriculas*, if we may so describe them, are *P. viscosa*, *P. hirsuta*, *P. villosa*, *P. marginata*, *P. Chusiana* and *P. minima*, with that magnificent hybrid between the two last *P. intermedia*.

Mention must be made of two other alpine species and then we must turn to another genus. The species are *P. Albonii*, which though rare in the Alps is not difficult in the rock garden club. It is, indeed far easier there than in an alpine house, but if handled with judgment it can be managed there. The other species, *P. integrifolia*, is an abundant one. It is quite distinct and easy, but the flowers are not particularly pleasing in colour.

A BEAUTIFUL ALPINE AURICULA, PRIMULA PUBESCENS MRS. J. H. WILSON.

This is often listed as a variety of *P. hirsuta*.

To be continued.

The Raising of Freesias from Seed

SOON the pots of fragrant Freesias will be filling the air of the greenhouse with delicious perfume—a perfume that is distinct from all other flowers, unique in its qualities. Perhaps you have a few of the newer coloured forms that of late years have so changed the possibilities of the whole family? for the Freesia is in a state of transition, having left behind the three or four standard varieties which had been grown for generations. New colours and varying habits have come into the family life and the offspring have started upon a new road of which it is impossible to forecast the end.

This brings me to the point of my note, the intermarriage of some of these new forms and raising the seeds so secured, which very possibly may reveal some still further advance on existing varieties. Once the balance of a plant has been affected and the germ cell changed it is capable of sudden jumps that never happen in the ordinary course of life at all, and the Freesia is in this state at the present time. Raising from seeds (so lengthy and tedious a process with many bulbous flowers) is a rapid one, for the Freesia is a quick-turn plant, and you have the joy of seeing the tangible result of your experiment within twelve months of carrying it out. Select your parents with a definite aim in view. Either you wish to strengthen colour by intermarrying two of similar shade, you desire to improve habit by using pollen from a weak-stemmed variety of good colour upon the stigma of a sturdier form, or you wish to aim at something absolutely new by combining two diverse colours. In either case, have a definite goal and do not mangle indiscriminately in the hope of hitting the bull's-eye somewhere.

After crossing, take care of your plants. Very often plants that are carrying seed capsules take longer to mature their foliage than those grown in the ordinary way, and no attempt must be made to hasten this. Secure the maximum amount of fertility by the maximum of ripeness. Seed can be sown either in April or August, the April sowing often coinciding with the period at which the seed matures. Sow in a rich but light compost, sandy loam with a little finely crumbled leaf mould being good. Well drain the pans and cover the seeds but shallowly with soil. Even moisture is important, though care must

be taken not to get the soil too wet. Half a dozen seeds are sufficient for a 5in. pan, and the brisker the temperature the more quickly the seeds germinate. Five or six weeks are generally sufficient, and once well through the soil the pans should be removed to a lower temperature. Keep them in a good light, so as to avoid drawing up thin and lanky, a complaint to which Freesias are especially prone if grown in shade. Only the brightest sunshine should be screened from the plants during summer, but sufficient shading is important to prevent scalding. By sowing

A BEAUTIFUL HYBRID FREESIA.

half a dozen seeds in a 5in. pan any necessity for repotting is avoided, but where they have been sown more closely than this you must handle with extreme care, for they are extremely brittle, and it is the easiest possible matter to break the small plants by rough or careless usage and thus lose what might prove a lovely flower.

Another way, of course, would be to sow singly each seed in a 3/4in. pot that would see the resultant plant through to maturity; but this demands a considerable amount of space if much crossing is done and there is a bountiful crop of seed, so that generally several in a pot is better.

Through the summer the plants can be grown outside, of course, which will relieve the pressure on the greenhouse accommodation for the time

being. An open, though somewhat shaded, position should be chosen for them, especially if the single pot system is adopted, for where exposed to full sunlight it is quite impossible to keep these small pots watered through a spell of real drought, for watering would certainly be required by some of them two and even three times in a day. Before frosts occur in autumn the pots must be brought inside again, where a comfortable temperature of between 50° and 60° is maintained, and should be ranged on a shelf near the glass where their requirements as to watering, etc., can be examined with facility.

Watch for the first signs of foliage toppling over, and prevent this by looping each plant lightly to a thin stake, so that it will permit growth to go forward and at the same time maintain it in an upright position. Then comes the interesting point at which the buds appear—buds so crammed with possibilities. Will they be new? Will they be worth the while? Time alone will prove, but you will at least have had a fascinating experiment and, possibly, a big reward.

BULBIST.

Perpetual Border Carnations and Allwoodii

Mr. Montagu Allwood's own views on the cultivation of the Hardy Perpetual Border Carnations and Dianthus Allwoodii.

THE two most recent and important developments of the Carnation, the Perpetual Border Carnation and *Dianthus Allwoodii*, are of great interest to all horticulturists. The object in raising these new hardy races was to produce plants giving the same perfect formation of flower as the old Border Carnation and Common Pink types, yet harder in constitution and perpetual flowering outdoors from spring to late winter. That we have succeeded is evident by the flowers we have before us at the present time, and in the many thousands of seedlings under test there is found a larger range of colour than in any other section of the Carnation family.

Regarding the propagation of these new races of *Dianthus*, the same system is adopted here as with the Perpetual-flowering Carnation, except that the best period for rooting the cuttings is from June to September. This should be done in cold frames or greenhouses, double shading being necessary in excessively hot weather to minimise the hot, dry atmosphere. After rooting, they are potted direct into 5in. pots and, when established, receive one stopping only at the sixth or eighth joint, after which they are ready for planting direct into the garden, care being taken that the young plants do not become checked or starved in the small pots before planting.

As regards general cultivation, this is identical with that of the old-fashioned Border Carnation. In common with all flowering plants, they flourish best in an open position which has a direct light and is not overshadowed by trees or buildings; in fact, they will flourish anywhere except in complete shade. It is not wise to plant the young plants closer together than 6ins., or further apart than 18ins. Our plants, which we leave in the same position for three years on our nursery beds, are planted at 12ins. apart, but for an edging rows, would be the correct distance to leave between them; that is, from stem to stem.

Such reasonable and hardy plants as *Allwoodii* and Perpetual Border Carnations, which are practically fool-proof and will grow on a railway bank,

naturally are not exacting as to soils, and will flourish in those of any texture if the following simple advice is observed. In the case of very light, sandy soil, which as a rule is poor and lacks plant food, autumn and early spring planting is advisable. The advantage of light soil is that the plants have free drainage during winter and commence to grow earlier in spring. A heavy dusting of pulverised chalk dug into light soil gives it substance. A top-dressing of Carnation food, given from April to September, is beneficial. Hoeing the surface soil once each week in bright, dry weather will help the roots to keep cool and moist, and also assist the Carnation food (which should be organic, and not chemical) to perform its work. Better results are obtained from repeated top-dressings and hoeing than from digging in large quantities of yard manure.

The soil at our Wivelsfield Nurseries is heavy clay, but at our Plumpton Nurseries it is medium loam, and this is ideal. Allwoodii and the Perpetual Border Carnation were raised and reared, however, at Wivelsfield Nurseries. Heavy soil is best deeply dug or bastard trenched in early autumn, and left as rough as possible so that winter frosts can pulverise it. A dusting of lime will help to break the soil down. Old yard manure or other enriching medium is best added when the surface of the soil is lightly forked, or Canterbury-hoed over, in spring. In heavy soil all seasons are favourable for planting, with the exception of late autumn and winter.

The soil in an old town garden is often sour and infested with earthworms, through lack of

cultivation. This soil simply wants correct treatment to make it ideal for Allwoodii. A dusting of lime is the most valuable addition. Use just sufficient to look like a light snowstorm, then deeply dig the soil, leaving it in big lumps and as rough as possible, so that the light, air and sun can sweeten it, when it should be left for a few weeks. The soil is best enriched during spring and summer with Carnation food, while hoeing during bright, dry weather is of the greatest possible assistance to the plants.

It seems unnecessary to describe the various ways of growing Allwoodii and Perpetual Border Carnations, because they will grow in any place where plants will flourish and flower. This alone will suggest to the mind of an enthusiastic grower innumerable ways and means of cultivating them. As carpet plants under standard Roses they are ideal, being shallow rooted, while Roses are deep rooted. In window-boxes or lawn vases no plant can look more beautiful or supply a greater show of bloom from May to October. We have seen Allwoodii making a brave display in pots on window-sills. Naturally, as edging plants or in beds by themselves one first thinks of growing them, but in rockeries or dry walls they seem at home. If you can plant them with a background of dark evergreen shrubs their blue-green foliage is, in the winter, seen to great advantage. These new flowers, with their old-world charm, have only to become known to be loved by all. A bed or edging of one variety gives the appearance of a drift of colour and can be fitted into a piece of perfect colour harmony. MONTAGU C. ALLWOOD

every advantage that can be provided by man and Nature contributes to success.

Though I have spoken so far of either sun or shade in an alternative sense, the ideal rock garden is a combination of both, where one passes from sunland into shadow and the plants are varied accordingly. Another excellent way where space is ample—is to pass from the sunny rock garden, gradually, towards a clump of trees that are the shade-makers and, by the restrained use of a few bold rocks and a good deal of short turf etc., pass into a really natural little piece of miniature alpine pasture—a refined and improved pasture, if one may dare to say this of Nature's handiwork—with all the coarser, commoner plants weeded out, the ultra ultimate super-planting, as though she had concentrated there in our collection samples of her best and greatest gift to one favoured devotee. Here, one large rock should stand cracked and split into clefts and crevices, holding back a large body of earth behind it, so that Haberleas and Ramondias can be packed in horizontally and form immense rosettes of deep green wrinkled, hairy leaves, from the centre of which—each June—push up scores of stems of rosy purple, orange-centred flowers. It is fairly generally known now that both these plants must be planted horizontally so as to throw the rain from the centres and prevent wet lodging among the hairy leaves, but at the same time they quickly perish if dry. They root very deeply, and great care must be taken in packing them to see that the roots really can penetrate far into a large body of peaty loam, that the soil completely surrounds the roots and that adjoining cracks are filled as well, so that cold winds cannot destroy the roots by blowing through and drying out the earth.

Among the short grass is the natural home of numberless hardy Primulas, and never do they appear more captivating than when seen in such a setting. What can compare with a mossy grass bank in February and March filled with our native Primrose, for instance? And in their natural habitat, remember, this is how all the hardy Primulas grow. It is the gardener that

THE SHADED ROCK GARDEN

Some of the many plants suitable for the shaded parts of the rock garden are touched upon below.

FROM the plantsman's lists, the almost unlimited books and articles that have been written on the subject of alpine and rock plants, and the constant reiteration of the phrases "must have full sun," "a position fully exposed to the sun," etc., we are in danger of losing sight entirely of the rock plants that not only thrive in, but demand shade if we are to obtain the finest and best examples of them. First of all, let us get this point absolutely clear and distinct. There is shade—and shade; the natural, cool, grateful shade, formed either by the shadow of a large rock or a north aspect, where the soil is always damp and where colonies of Primulas, many Saxifrages, Haberleas, dwarf bulbs, Ramondias etc., revel and turn this into a delicious little wonderland of captivating flower and foliage—that is the kind of shade I had in mind when I wrote my title. Then there is the shade that is utterly hopeless and had better be turned into a plantation of strong-growing hardy Ferns and Funkias—the shade that is beneath tree boughs where, whenever it rains the earth is soddened with drip and stagnant wet and where no self-respecting rock plant will live through a single winter. Not long ago a lady asked me to go and see her "rock garden" where conditions similar to the latter obtained, and I must candidly admit that, among the few plants that had managed to continue their existence, very few indeed would have been recognised as alpine by the genuine alpine lover. Where, however, a shaded slope exists right clear out in the open, with no overhanging boughs, and where sufficient moisture-retaining material, such as peat, etc., can be added to the soil, we may have a rock garden

upon which the sun never shines in his strength and a rock garden as packed with choice plants and flowers as the most favoured suntrap where

A CANDIDATE FOR THE SHADY ROCK GARDEN—HOUSTONIA CŒRULEA.

has segregated them and dropped them into little pockets of rock and earth, divorced from the short, close verdant grass setting that serves to keep the roots evenly moist at all seasons and cool in summer. You must, of course, choose varieties that are suitable for this, and the large majority are on your side, among which the following are all good: *P. Allionii*, *calycina*, *carniolica*, *denticulata*, *hirsuta*, *imperialis*, *latifolia*, *megaseæfolia*, *pubescens alba* and *villosa*. Do not overlook the absolute importance of procuring a really dwarf, close-growing, wiry grass for the purpose of surrounding such plants, or they will be buried among the deep lush growth. A fine little thing that makes itself at home everywhere and—if the idea is being worked out on a small scale—might well take the place of turf is *Arenaria balearica*, a wee green carpeter covered with tiny white flowers. This will, if there is sufficient dampness, run all over the place, even on the bare rock face, taking the shape of the rock itself as it runs. The effect of a little patch of this surrounding a dozen irregularly planted plants of *P. Bulleyana* is simply superb. Close down on the earth a dense carpet of shining green leaves starred with tiny eye-like white flowers, then the *Primula*, a cunning plant which disguises itself as the common Primrose until its flowers appear. These, however, are in whorls, on stems about a foot high, with rich golden yellow flowers tinted on the outside with apricot. Speaking of delightful carpeters, do not overlook *Tiarella cordifolia* for use among taller plants, for this will really grow itself and run about by means of runners as freely as the Strawberry.

A notable long-flowering plant is *Chrysogonum virginianum*, and this we can use anywhere in the shaded rock garden with the utmost confidence, for it persistently bears bright golden flowers even under the dense shade of trees, and that for months. Another continuous bloomer that will not disappoint is *Claytonia*, of which the two varieties that I like best are *C. caroliniana*, with charming rosy flowers in July, and *C. sibirica*, a trailing-habited plant with bronze foliage and rose flowers in racemes. One species of *Cortusa*—*Matthioli*—with its umbels of drooping purple flowers, repays massing near its relatives, the *Primulas*, and gives a continuous effect from April to June. A very choice shade lover is *Galax aphylla*, the lovely Wand Flower. This is a North American creeping plant that throws up fine spikes of white flowers in summer on stems a foot high, though to many its greatest effect does not appear until autumn, when the large evergreen leaves assume their winter dress of bronze and crimson. While not easy to grow, the *Blechns*—*Houstonia cœrulea*—is worth any amount of trouble to ensure its complete happiness. Set the plants in the shady rock garden in an equal mixture of peat, leaf-mould, sand and fibrous loam. Though they like plenty of water in summer, winter wet is fatal, and a sheet of glass over them (as with the wet-hating *Androsaces*) is essential in winter. This brings to mind a very choice species of these *Androsaces*—*foliosa*. This is, again, a very continuous bloomer, lasting from May to September, loving limestone and flowering in large umbels of rosy lilac blooms.

Wulfenias, though generally recommended for raised parts of the bog garden, do well in the shady rock garden, and both of the two species are scarce plants, coming from the Himalayas and needing similar treatment to the *Primulas*: that is, a damp, peaty soil and cool shade for the roots. Do not omit the numberless indispensable corms, bulbs and tubers which add so much charm in spring and autumn. The wealth of material to hand in this class is astounding, for the wee miniature *Narcissi*, *Bulboodium*, *minimus*, etc.,

with *Muscari*, *Ornithogalums*, *Fritillarias*, *Erythroniums* and hosts of others—transform the whole scene into a veritable fairyland of beauty in spring, while autumn-flowering varieties of the hardy *Cyclamens*, etc., are no less serviceable in autumn.

Where my suggestion of letting the shady rock garden run out towards trees as an extension of the ordinary rock garden is followed out, you will find that there comes a definitely marked line beyond which, towards the trunk of the tree, the grass becomes sparser and sparser and finally all vegetation ceases. What is to be done, you say, with this? To leave it bare is an eyesore, yet Nature herself has refused to have anything more to do with it. Oh, no, she has not—never was a greater error! Put in a few bushes of *Hypericum*. This genus contains a large number

of species, sufficiently diverse to add a great deal of interest, and possessing the advantage of being practically ever-blooming so far as summer and autumn are concerned; while the dwarf *Chrysogonum*, to which allusion has already been made, is splendid in early spring to produce a gold effect before the *Hypericums* begin. Greatest of all, however, are the common woodland *Bluebells*, massed in hundreds—ay, thousands, if space permit—so that as one looks ahead in the early spring days the whole earth seems but an intenser reflex of the cloudless sky above. Yes, far from the shady portion of the rock garden being a matter to bemoan, it is an opportunity to grasp—an opportunity the possibilities of which have been but briefly sketched in the above note. H. W. CANNING-WRIGHT.

THE YEW AND ITS VARIETIES

Some attributes and peculiarities of one of the most valuable of our hardy evergreen trees, with a list of the more worthy forms.

THE Yews are widely distributed trees in a wild state. Opinions differ in regard to their specific nomenclature. Some botanists make as many as seven distinct species, while others incline to the belief that they are all varieties, or geographical forms of one species, *Taxus baccata*. The behaviour of the common Yew under cultivation rather confirms the latter view, for in gardens there is as much or even more difference between cultivated varieties than between some of the so-called species, the variations in which are probably due to climate and soil. The common Yew is a native of Europe (including Britain) and North Africa, and extends in Asia as far as the Himalayas. The

Chinese form is known as *sinensis*; the Japanese, *cuspidata*; the Canadian, *canadensis*; and the Pacific Coast Yew, *brevifolia*. The Yew is also recorded from Mexico and Florida, but these forms are, apparently, not in cultivation.

Among the numerous hardy evergreen trees and shrubs planted freely in the pleasure grounds and shrubberies the Yew is one of the most valuable of them all. As specimen trees on the lawn the value of the numerous beautiful and distinct varieties is by no means fully recognised. Some are tall, imposing and graceful in outline; others of moderate height and wide spreading; several compact in habit or rich in colour; while the fastigate character of the Irish Yew is well known.

In the shrubbery border the Yew may be planted as a screen, where it will thrive in sun or shade, and form an excellent background for flowering trees, shrubs and herbaceous plants. For hedges its only serious rival is the Holly, while for topiary work the Yew is unequalled, standing constant clipping year after year for an apparently indefinite period, certainly for a couple of hundred years.

The Yew is dioecious, very rarely monoecious, so that if it is desired to secure attractive fruits in quantity, male and female trees must be planted in close proximity. The male trees, as a rule, produce pollen in abundance, the wind distributing it when it is ripe in almost cloud-like form.

The Yew thrives in most soils and positions, is very hardy and useful to plant in exposed situations. Liberal pruning does not harm the trees, so that it is quite easy to keep the Yew tree within bounds when becoming too large for its position or crowding

A FINE AVENUE OF IRISH YEW (*TAXUS BACCATA FASTIGIATA*) AT LAMPORF HALL.

a neighbour in the shrubbery. Very old trees, Yew hedges and lawn specimens derive benefit from liquid manure or a dressing of old decayed farmyard manure.

Seeds provide a ready means of propagating the common Yew in quantity. Though most of

or Pacific Coast Yew; canadensis, the Canadian Yew, a low-spreading shrub up to about 1ft high; cuspidata, the Japanese Yew, having a yellow tinge on the underside of the leaves; Dovastoni, the Westfelton Yew, horizontal branches and pendulous branchlets, forming beautiful specimen

not stiff, and will attain a height of 6ft to 8ft. It is suitable for covering large stones on the rock garden or as isolated specimens near the lawn, while it should be useful for making a hedge around a formal Rose garden. The foliage is pleasing at all times, and the flowers are followed by hips of a dark crimson colour. No pruning is needed except cutting out a few of the old growths when they become crowded.

R. WILLMOTTIE.—This pretty and very distinct species was named after the well known amateur, Miss Willmott of Warley Place, and it was discovered in Western China by Messrs. Veitch's collector, Wilson, some fifteen years ago. The single rose-carmine flowers, which are about 2in. across, are freely produced during June. They are borne singly on short stems on wood of the previous year's growth. The fruits are orange-red, and the elegant foliage and arching growths add greatly to the value of a species which is quite distinct from the majority of Roses in cultivation.

R. MOYESII.—No species or hybrid of recent introduction has attracted so much attention as this delightful plant. It is quite distinct in habit, and no other Rose produces just that shade of colour—it stands alone. It was first collected by Mr. A. E. Pratt about 1890 in the mountains of Szechuan

at an elevation from 7,000ft. to 9,000ft., and it was named in honour of the Rev. J. Moyes, a missionary in China. Introduced to cultivation by Messrs. Veitch in 1903, it was when shown by them on June 6th, 1908, given an award of merit by the R.H.S. When it was exhibited by Mr. J. C. Allgrove on June 30th, 1916, it gained the coveted first-class certificate, an award thoroughly well deserved. *R. Moyesii* is quite hardy, a free grower, and will form a bush 6ft. to 10ft. high. The flowers are about 2ins. across, dark red, the younger blooms being a shade of cardinal red, while an additional charm is the large cluster of tawny yellow stamens. The erect growths are covered with stout prickles, the leaves are small, and the pear-shaped orange-red hips are a decided acquisition during the autumn months.

When *R. Moyesii* was growing at Messrs. Veitch's Coombe Wood Nursery the plants exhibited some variation in colour, and the best form was figured in the *Botanical Magazine*, t. 8338. Messrs. Veitch only increased their stock from the best variety, but since the dispersal of that famous form no doubt a number of *R. Moyesii* have been raised from seeds, and consequently inferior varieties are to be found in some gardens today.

It is increased by budding and grafting, but I think such a vigorous plant should be on its own roots, then we are not likely to be bothered with suckers. This Rose is allied to *R. macrophylla*, which is found both in China and the Himalayas.

Both *R. Moyesii* and *R. macrophylla* are at all times very noteworthy plants in the garden, but never more so than in autumn, when their curious bottle-shaped hips change colour. In *R. macrophylla* these are crowned by the very large persistent sepals.

T. W. B.

SOME OF THE WONDERFUL TOPIARY (ENGLISH YEW) AT ELVASTON CASTLE.

the named varieties are seedling variations, it is necessary to reproduce these from cuttings. Among a considerable number of seedlings raised from the varieties *adpressa* and *fastigiata* in the nursery here not one has come true. They all resemble more the common Yew than either of the seed-bearing trees. August is a good time to insert cuttings in sandy soil under bell-glasses or handlights. Make them of the current season's growth, some 2ins. long, with a slight heel of old wood.

The average height of the trees is from 25ft. to 50ft., though at Midhurst there are specimens in a grove 70ft. to 80ft. high. Grown in the open the Yew is frequently wide spreading. At Whittingham there is a tree 125yds. in circumference. One of the largest trunks recorded is in Darley Dale churchyard with a girth of 27ft. In many widely distributed places there are noteworthy specimens, these being frequently associated with churches and buildings of historic interest.

Topiary work, though not so popular as formerly, is represented by many fine examples, one of the best being at Elvaston Castle, Derbyshire. Among the older school of gardeners clipped Yews still have many admirers, being an interesting and remarkable phase of arboriculture. Associated with old formal castles and mansions, the art of topiary work may be effectively employed, as Yew stands particularly well cutting into extraordinary shapes and forms.

An excuse sometimes given against the use of the common Yew in the pleasure grounds as a specimen tree is its sombre appearance. This does not hold good with many of the beautiful varieties. The most distinct and pleasing of these include *adpressa*, *adpressa stricta* and *adpressa aurea*, forms with smaller leaves; *aurea* and *Barroni*, golden Yews, *brevifolia*, the Californian

trees. *Horizontalis* is similar, but the branchlets are not pendulous—*elegantissima* is a golden-leaved form of it; *pendula*, *procumbens* and *ericoides* are dwarf forms suitable for the rock garden; *fructu-luteo* has attractive golden fruits; while *fastigiata*, the Irish Yew and its golden variety *amea* are well known forms.

Kew.

A. OSTOR.

SOME WILD ROSES

The simple elegance of the single blossom appeals almost to everyone. This is one of the principal charms of the Rose species.

DURING the last twenty years a number of species of Roses have been introduced from China, and although they do not command the attention bestowed on the various Hybrid Teas, they nevertheless deserve a place in every garden where space can be found for them. Wild Roses appeal to me, short though their flowering season be, for in autumn the numerous highly coloured hips produced by some species render them conspicuous and exceedingly bright at a time when most other plants are past their best. The finest effect is brought about by grouping the various species in the shrubbery border, on the fringe of the wild garden, or wherever they can be allowed to ramble without much pruning. Thinning out the old growths is all the pruning they need. One of the most noteworthy is *R. HUGONIS*, introduced from China by the French missionary, Peter Hugo, some twenty years ago. The single sulphur-yellow flowers about 2ins. across, appear towards the end of May, the graceful arching growths being more or less clothed with blooms. The habit of the plant is semi-erect and certainly

PLANTING SUGGESTIONS FOR THE NORTH BORDER

SOME years ago I was invited to advise a friend on the planting of a north border, backed with a fairly high brick wall. Herbaceous plants were preferred, as these would form a permanent feature entailing the output of but little labour or expense in their upkeep. Recently I have been afforded an opportunity of viewing the results obtained by the adoption of my recommendations and, as the whole proved satisfactory, I am passing the advice on for the benefit of the many who require similar guidance.

When first I inspected the site two fine specimens of the Morello Cherry furnished part of the wall space available, and the retention of these useful trees was advocated. In addition to the beauty and great utility of the fruits in late summer, the flowers make a delightful display in spring; moreover, the Morello Cherry does admirably when accommodated on a north wall. To complete the draping of the background, specimens of *Crataegus Pyracantha* (the Fire Thorn) and *Cotoneaster microphylla* (Rock Spray) were planted. The former is beautiful enough in spring, but really glorious in autumn with its vivid scarlet berries; while the chaste white flowers of the Rock Spray are quite a feature during the whole of June.

Among the noble plants commanding attention at the back of the border, varieties of *Helianthus* (Perennial Sunflower) hold their own, and in late autumn the varieties Rev. Wolley Dodd and Miss Mellish provide a welcome splash of gold. The feathery white plumes of *Spiraea Aruncus* (Goat's Beard) are effective in July. Of the Monkshoods (*Aconitums*), the varieties *Fischeri* and *Wilsoni* do best on this north border. The former carries pale blue flowers on 3ft. stems in autumn, while the latter attains a greater height and its darker blue flowers are conspicuous in August. Michaelmas Daisies, such as *Climax*, *Blue Bird*, *Orion*, *Onward*, *Bedding Queen* and *Mrs. J. F. Ravner*, vary in colour and height greatly, but all do well here and are attractive from August onwards into autumn.

Varieties of *Anemone japonica* find hosts of admirers, and clumps of Spanish Iris along the foreground of the border never fail to provoke praise. Campanulas in variety (Canterbury Bells are the most satisfactory) are pressed into service, while towards the front bold, irregular groups of the charming Columbine make a wonderfully pretty display. Fritillaries are a great feature, the Crown Imperials and *F. Meleagris* (Snakes-head) being the best of the various species tried. Certain annuals, such as *Virginian Stocks*, *Viscarias*, *Candytufts* and *Calendulas*, produce a gay effect in summer, and a spring display is made certain by the planting of commoner bulbs, such as *Crocuses* and *Daffodils*.

The edging of this border is entirely formed by a wide drift of *London Pride* (*Saxifraga umbrosa*), and right well does this accommodating plant justify the complete confidence reposed in it to shine under difficult circumstances.

Prior to planting any of the plants mentioned my friend dug the whole of the site to a depth of 2ft. He rightly retained the top spit in its original position, and incorporated liberal quantities of ashes from the garden bonfire. This latter naturally sweetened the soil, while the deep working improved the drainage. Without spade work of this kind plants cannot be expected to succeed on a cold north border. Provide a healthy rooting medium and the north border may yet

be a show corner of the garden. In seasons such as 1921 it is, at any rate, easier to keep plants in a flourishing condition on a north

border than elsewhere; while in the wettest seasons, such a border need not become soddened. F. W. MILES.

NOTES FROM GLASNEVIN

By LADY MOORE.

THAT beautiful species of Travellers' Joy (*Clematis smilacifolia*), of which I sent you a flowering spray and which is so well named from its large, handsome leaves, resembling those of *Smilax latifolia*, is little known. In Vol. II of the third series of Curtis's *Botanical Magazine*, October, 1846, it is described. The account states: "This plant was introduced from Java to the stoves of this country, where it flowers in June and July, and reintroduced by Veitch of Exeter. Being a mountain species, it will perhaps succeed in a greenhouse, where it would make a handsome climber."

Some years ago seeds of *Clematis smilacifolia* were sent from Siam by Mr. Kerr, a former student of Trinity College, Dublin, to Professor Henry Dixon, who gave a plant to Glasnevin. It flowered in November and December, the accompanying photograph being taken from our plant. The stem extends a great length and is glabrous; large, undivided, cordate, ovate leaves, slightly serrated, are marked with deep nerves, the racemes axillary. The flowers, which are very numerous, are ovate in the bud stage and of a rusty orange colour, opening into four oblong, lanceolate, subcoriaceous, acute sepals, which soon turn back. They are of a rich purple colour, which becomes darker every day, and are covered with a soft down. The numerous pistils are white, long and feathery. The perfume is very sweet and fills the whole corridor where the plant is grown, at a night temperature of 50°. The petals of the flower are thick and fleshy, like a *Magnolia* flower, and not of the thin, papery substance usual in the *Clematis* family. The flowers of the Siam plant are much larger than those figured in the *Botanical Magazine*; they are fully 1½ ins. across.

The photograph sent was taken by Miss E. V. Miller.

I also sent a bit of *Lonicera Henryii* in fruit. This was grown on a north wall. The flower is not very conspicuous, but the racemes of purple black berries are very effective and make most beautiful house decoration, especially in a room with a light-coloured wallpaper. The leaves hold well into January.

That very sweet-smelling Honeysuckle, *Lonicera Standishii*, is always the earliest of the winter

flowering varieties. This year it opened its blossoms in November. It is much more generous with its flowers than *Lonicera fragrantissima*,

THE HANDSOME CLEMATIS SMILACIFOLIA.

and the clean, fragrant perfume is just as sweet. The leaves of *L. Standishii* are large, rough and lanceolate; those of *L. fragrantissima* are small, rounded and of a delicate green. *L. Standishii* strikes well from cuttings.

The unusual heat of 1921 has had a most beneficial effect on *Chimonanthus fragrans*. The wood was well ripened, and the result is a crop of flowers densely packed on every twig. The perfume fills the air on a sunny day. No garden with a wall should be without this lovely Chinese shrub.

[Like most fleshy textured greenhouse plants, *Clematis smilacifolia* is not a good traveller, so that it was fortunate Lady Moore was able to send a photograph—Ed.]

CORRESPONDENCE

A NATIONAL DAFFODIL SOCIETY?

"In these days we are a trifle overstocked with officials, and official machinery. If the Daffodil could speak for itself, I imagine it would plead for a quiet life."—G. H. ENGLEHEART in THE GARDEN, page 654.)

REQUIESCANT.

Let them dance their dance in peace, that happy band

Of brothers and sisters, young with youth eternal!

You think to worship? And do not understand
How gentle spirits hate the din infernal
Of cymbals, and sounding brass, and zeal irrational,
And damnèd iteration of that word "National"?

Not noise, not noise the incense they approve,
But the rapt homage mute of prince or boor.
And, giving what they take, those glad folk move,
Swinging their censers over mead and moor,
But what they hate—that hate they can, 'tis pity—
Is the solemn official fuss of a Committee.

The breezy hillside, dell, and stilly glade,
Their sylvan haunts—how I delight to rummage 'em!
And meet the dancing Daffodillies, not arrayed
In serried ranks at Vincent Square or Brummagem,
But far from the busy crowd's oppressive rattle,
Its fume, its fret, its official tittle-tattle.

How they hate a fuss! That galaxy of glory,
Of gods and goddesses, emperors and kings,
And damsels fair, and knights of song and story,
And saints, and poets, soaring on eagle wings—
Cædmon and, Chieftain of the Clan Poeticus,
Serene-eyed Horace—how they hate a fuss!

SOMERS.

IN my letter of November 26 I stated that the issue at the meeting in 1911 was not if there should be a National Daffodil Society, but whether or no the Midland should "constitute itself" the National Daffodil Society. Mr. Jacob tells me that there was no such proposal before the meeting. I accept the correction, and as no good purpose would be served by discussing it further, I will only express my regret for the error. I was glad to see Mr. Cranfield's letter of December 10—his practical and open-minded views, and that he is willing to take the matter up again. If the proposed meeting in March can be arranged, it will provide the opportunity for making a definite start and the appointment of an organising committee, which, as Mr. Cranfield suggests, when once the general principles are accepted, would discuss the various proposals from a practical point of view. I do not think, however, that we can expect to obtain the opinions of the general gardening public at any meeting. The public is notoriously inarticulate, and it is, in fact, impossible to get such general opinion beforehand by any available means. It can only be divined or estimated by disinterested observation of analogous cases. To do so cannot with any justice be called theorising. It is eminently practical being simply considering the point of view of the average man rather than one's own particular interests. The neglect to do this too often spells failure or something very like it. Can anyone doubt, however, the success of a National Daffodil Society conceived on broad lines, and not merely as a specialist's or fancier's society, when we consider not only that the Daffodil is an incomparable flower, still with infinite possibilities of development, but that

it reigns supreme in the garden for nearly two months of the year without actual or possible rival? Let us, then, boldly aim to have a society worthy of this Queen of Spring, for with such a flower failure is surely impossible. Mr. Cranfield remarks that "Daffodil growers, by comparison, are not a numerous body," but, from the context, he is evidently thinking of those who are specially interested. Those who grow at least some Daffodils must be nearly as numerous as Rose or Sweet Pea growers. If they are not, they should be! With the interest which such a society will stimulate, not only will Daffodils be more widely grown, but more people will learn to appreciate the immensely improved varieties, many of which are now available in quantity. These a really popular society will bring to their knowledge.—A. J. BLISS.

ONE WONDERS WHY.

ONE often wonders why some plants do not become more common than they are. There, surely, are many people who appreciate quiet beauty. How is it, then, that such a plant as *Veltheimia glauca* is so seldom to be seen in greenhouses? It is almost, if not quite, as long suffering as a *Nerine* or as its brother with the shining green leaves, *Veltheimia viridifolia*. Here, after two years of neglect, it is as flourishing as ever, and I have now five nice rosy pink to blush spikes of bloom, which are very pleasing on account of the interior of the mouth of the tubular perianth being of a deep hellebore red (Ridway's Colour Chart). I was induced to grow *Veltheimias* in the hope that a cross might be effected between them and my favourite *Lachenalias*; but, although I have gone on the old adage of "if at first you don't succeed, try, try, try again," I can only report "nothing doing." Now I have managed to increase the length of stem and the number of flowers on a *Lachenalia* spike. I am getting reconciled to the disappointment and am able to say to friend *Veltheimia*, "I think I shall be able to do without your help in this matter, but I shall always be glad to have you as one of the inmates of my greenhouse." The general appearance of a *Veltheimia* spike reminds one of the Red-hot Pokers, but in the place of orange and red shades we get rosy pinks and shades of blush. The glaucous foliage of *V. glauca* makes it at all times a beautiful plant.—JOSEPH JACOB.

THE MUSK ROSE.

THE Musk Rose (*Rosa moschata*) is one of the best of the rambling Roses both from an ornamental point of view and because of its delicious scent. In late June or early July it is a conspicuous feature with its numerous corymbs

of whitish flowers with bright yellow stamens—the inflorescences being often a foot across. Although it can be grown as a bush plant, to see it at its best it should be allowed to ramble at will, when it will throw out vigorous shoots roft or 12ft. in length, which, the following year, form graceful arches of flowers. The photograph I send is of a plant rambling over a large *Pinus austriaca*, 48ft. high, which forms an excellent background when the Rose is in bloom. The native habitat of *Rosa moschata* extends from South Europe to India. Introduced in 1500, there are several varieties—*Brunonii*, with glaucous leaves; *Pissardii*, with pink-tinged flowers; and *flore-pleno*, a double-flowered variety.—F. G. PRESTON, *Cambridge Botanic Garden*.

THE FLOWERING OF IRIS UNGUICULARIS.

I HAVE had these in my garden for twelve years and they have flowered quite fairly well, usually in January. Last year they began to flower early in November and are in bloom now. This was the first year that they have really made a great show in the garden. There have been more than double the number of blossoms at the same time and the blooming has gone on for many weeks.—"SOMERSET."

THE CULTURE OF DAPHNE CNEORUM.

I HAVE always treated *Daphne Cneorum* as a shrub which thrives best in a mixture of sandy peat and leaf-mould, but I have been informed that the species will do just as well in a loamy soil. As I cannot altogether accept this, I should like readers of THE GARDEN to give their views. Is a mixture of good fibrous peat, leaf-mould and

A FINE PLANT OF ROSA MOSCHATATA.

sand with partial shade or a good loamy soil most suitable? Also if any reader has achieved much success with *Daphne Cneorum* for forcing and winter garden use.—R. J.

[*Daphne Cneorum*, in our experience, succeeds wherever *Rhododendrons* and *Azaleas* flourish. If it can be provided in addition with a stony root-run, so much the better.—E.D.]

THE CULTIVATION OF ALPINES IN SPHAGNUM MOSS.

FOR more than thirty years I have proclaimed the necessity of introducing the cultivation of alpinists in sphagnum moss, especially for hot

A CONTRAST FROM JAPAN.

and dry climates exposed to a broiling sun. I once saw in Italy (Pavia) a group of alpinists of the most delicate nature, such as *Arnica montana*, *Artemisia glacialis* and *Androsaces*, growing splendidly in full sun, but in a bed of sphagnum. Later on in the Genoa Botanic Gardens I saw *Azalea procumbens* Edelweiss, *Arnica*, some of the most delicate *Androsaces* and *Primulas* growing quite well in the same medium. Why could not we do this at Geneva, said I, and so, more than thirty years ago, I began to make experiments. The results were wonderfully good and encouraging. I obtained more than fifty flowers of *Soldanella* on one pan, and *Arnica* and *Androsace* and all the most delicate alpinists, especially those which hate lime, and which before I could not grow here because of the calcareous nature of my soil, flourished marvellously. They were, indeed, much finer than in their alpine homes.

Many of my friends have, since that time, tried the treatment and achieved good results. This applied, however, only to those living in dry climates and under fierce sunlight. In England, for instance, culture in sphagnum is very unsatisfactory. The functions of evaporation and consequent absorption of water by the roots are, of course, dependent upon sun heat. With such a moisture-retaining medium as sphagnum it is necessary that the air should be dry and the work of evaporation as active as possible.

After publishing in England the results of my first experiences, I received several letters from alpine growers who had failed in this method of cultivation. Some, however, in the South of England and also in Essex obtained good results. I have received, more recently, from Japan where the atmospheric conditions approximate to those

of England, a letter and some photographs all testifying to the great success of sphagnum culture for alpinists and other plants.

Dr. I. A. Tsujimura, of Odawara, Sagami, Japan, writes that he has been very successful with the cultivation of alpinists in sphagnum. "Not only," he says, "for plants. I sowed, too, some seeds on top of pressed sphagnum, uncovered by soil or sand, and they came up all right. Care must, of course, be taken not to let the plants get too wet if they are of the genera *Diapensia*, *Cassiope*, *Phyllodoce*, etc. For those, however, which are found naturally on marshy ground, such as many *Primulas*, I simply leave them outdoors even under heavy rain."

He sent me photographs, one of which I send you herewith, to show the difference between *Primula malacoides* grown in sphagnum and one raised in mixed soil. The big one is in sphagnum. They were sown together.

Here at Floraire I have a bed of sphagnum in which grow all the lime-hating plants and such delicate alpinists as *Eritrichium nanum*, *Androsace glacialis*, *Phyteuma Balbisii* and *P. comosum*, etc. That little marsh bed is a great source of joy, but it must not be forgotten that we have here a very dry continental climate.—H. CORREYON, *Floraire, Geneva*.

[Acting on M. Correyon's published advice, the Editor some years ago tried seed raising in sphagnum, and also the after-culture of certain genera in pots in the same medium. Only sorts considered likely were tried, but the experiment, as far as it went, was entirely successful. The most noteworthy successes were obtained with *Pinguiculas* of sorts, *Soldanellas*, the bog *Gentians* and *Eritrichium*—this, however, is not worth growing in Britain except as a curiosity. *Arnica montana* is, in England, quite easy to raise, and grows in peaty soil. A wide field of experiment would seem to be open with regard to some of the *Primulas*, the *Sarracenias*, *Cypripedium spectabile* and other moisture-loving plants.—E.D.]

THE SQUIRREL PLAGUE.

YOU may be interested in my experience of the squirrel nuisance. My garden backs on to Richmond Park and the depredations of the park (grey) squirrels have become noticeable of recent years. I have frequently seen a squirrel sitting on the party fence and stretching its paw down to pick the fruit of the Raspberries, Loganberries and Blackberries trained to the fence. One Sunday afternoon this summer I had considerable trouble in getting rid of one invader. I despatched him coming along the top of the fence and drove him back over the park wall. It was only about two minutes before he was back again, and it took six or seven chivvings to induce him to stay away—at least, as long as I was in the garden.—F. WYNN HELLINGS.

THE HARVEST OF THE SEA.

THIS phrase is usually considered to mean the bountiful supply of fish that the oceans contribute to the food of man, but recently I was struck by an entirely different aspect of the matter. For four days mountainous seas had been thundering upon the shore, washing and swirling as they fell with a crash on the rocks and sand. As one watched one could see that each wave as it broke was dark beneath, with masses and masses of seaweed torn from the depths beyond. Presently the tide retreated, and as it did so, left behind tons upon tons of weed. Then came numbers of men and a long procession of carts, the weed was raked together into great heaps, piled high upon the carts and, as they wended their way inland, the men flung further piles upon

the stone-walled parade, ready for carting later in the day when the sea should have returned and made further collecting impossible. Those who have gardens near the sea might do well, indeed, to consider far more seriously than they have hitherto done the benefits of seaweed as a manure, with its rich supplies of potash, salt and humus—especially in the vegetable garden. Peas, Beans, Celery and Leeks all luxuriate where it has been used in preparing the trenches in which the seeds are to be sown, while, of course, as a top-dressing to *Asparagus* beds it is unexcelled. The best way for using for garden purposes is to cart it to the garden and stack it in a similar way to that in which manure is stacked. If it is available at the same time a splendid plan is to mix and stack an equal bulk of animal manure and seaweed together. The admixture of manure greatly hastens decomposition, and such a heap should be ready for spreading on the ground at the end of about three months. At the expiration of this time the bulk will have reduced considerably and decomposition will have gone far enough for you to possess a heap of rich partially decayed material that can be spread on beds, borders and the vegetable plot with confidence. Where it is desired to use the weed alone, without animal manure, stack the heap in a similar way, but do not use for nine months, as decay is much slower.—H. W. C.-W.

A FREAK DAHLIA.

I ENCLOSE you a photograph of a Cactus Dahlia plant, Dorothy Hawes, which grew to a height of 10ft. 6ins. A 10ft. rod is seen standing against the plant, which is not one with

AN EXCEPTIONALLY TALL DAHLIA.

a single stem. It will be seen that there were four flowers fully out when the photograph was taken on September 17 last. Three had previously been cut. The flowers were all Sims, across. I cannot say what caused this plant to go up to such a height. Others of the same variety in the bed grew to 6ft. or 7ft. only. I know we do not want Dahlias so tall, but I thought the photograph might nevertheless be of interest.—W. G. CRAMP, *Strattham*.

FLOWERS IN BLOOM ON CHRISTMAS DAY.

YOU may be interested to see the following list of 139 different species of flowers which we counted on Christmas Day in two gardens here. As we experienced 4° of frost in the first week of December it is rather surprising to be able to find so many plants continuing to bloom. Erica Veitchii is much earlier than I have known it before, but, on the other hand, E. darleyensis (mediterranea hybrida) will not be in flower for some weeks; it generally opens before Christmas, but last summer it nearly died owing to the drought. None of the plants in flower has received any protection whatever; Abelia floribunda, A. grandiflora, Acacia dealbata, A. falcata, Alyssum saxatile, A. maritimum, Alstroemeria aurantiaca, Anthemis Kelwayi, Antirrhinum majus, Abutilon megapotamicum, Abutilon (large-flowered variety), Aster cordifolius, Anemone "St. Brigid," Arabis albidia, Aubrietia violacea, Berberis Darwini, B. Gagnepainii, Buddleia auriculata, B. Colvillei, Bomarea multiflora (in bud), Cassia corymbosa, Campanula muralis, C. persicifolia, Convolvulus Cneorum, C. mauritanicus, Cineraria (large-flowered and stellata), C. maritima, Cobaea scandens, Colletia cruciata, Cistus florentinus, Cheiranthus (Wallflower), Clematis calycina, C. cirrhosa, Coreopsis grandiflora, Choysya ternata, Crocus Imperati, Chrysanthemum indicum (many varieties), Cotoneaster sp., Coronilla glauca, C. emerus, Cytisus racemosus, Chimonanthus fragrans, Citrus Lemon (also newly set fruit), C. Orange, C. Shaddock, Clarkia, Camellia (red and white), Cyclamen Coum, Cydonia japonica, Daphne laureola, D. Mezereum, D. odora (japonica), Dendromecon rigidum, Dianthus (Carnations), D. (Pinks, Allwoodii, &c.), D. graniticus, Desfontainea spinosa, Erica Veitchii, Escallonia macrantha, Erysimum Peroffskianum, Eupatorium Weinmannianum, Erigeron mucronatus, Fatsia japonica (Aralia), Fuchsia microphylla, F. Cottinghami, F. garden hybrids (eight varieties), Geranium (Ivy-leaved varieties), Gentiana acaulis, Grevillea rosmarinifolia, Gerbera Jamesoni, Helianthemum (three varieties), Helleborus niger, Heuchera brizoides, Hydrangea hortensis, Hypericum patulum, Iberis sempervirens, Iris unguicularis (three varieties), Jasminum nudiflorum, Leptospermum scoparium, L. prostratum, L. rosmarinifolium, Lavender, Lonicera fragrantissima, L. Standishii, L. Periclymenum, Laburnum vulgare, Leycesteria formosa, Leonitis Leonurus, Linum flavum, Myrtus communis, Matthiola (Stock), Mazus repens, Narcissus Bulbocodium (Hoop Petticoat), Nandina domestica, Nicotiana affinis, Omphalodes cappadocica, O. verua, Olearia macrodonta, Philadelphus Lemoinei (variety), Pittosporum Tobira, Primula auricula, P. Julia, P. cashmeriana, P. vulgaris, P. malacoides, Pernettya mucronata, Phlox setacea, Pentstemon (many varieties), Roses (many Hybrid Teas, &c.), Reseda odorata, Romneya Conlteri, Rosmarinus officinalis, R. o. prostrata, Rhynchospermum jasmiioides, Salvia fulgens, S. rutilans, S. uliginosa, S. officinalis, Sparmannia africana, Solanum jasmiioides, S. capsicastrum, Spartium junceum, Sedum Bourgoi, Selizostelis coccinea, Spiraea

arguta, S. prunifolia fl.-pl., S. Thunbergi, Stylophorum diphyllum, Teucrium latifolium, Veronica cataractae, V. salicifolia, V. speciosa (several varieties), Valerian (Centranthus) Viburnum Tinus,

Verbena radicans, Viola tricolor (varieties), V. odorata (double and single), V. gracilis lutea and Yucca gloriosa.—N. G. HADDEN, *West Porlock, Somerset*.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Planning of Crops.—Whether the garden is large or small it is a sound and practical plan on the threshold of a New Year to formulate some scheme of cropping as a guide in allotting out each plot of ground to be occupied during the year. The system of a regular rotation of cropping is more applicable to large gardens, but this does not necessarily mean that the possessors or managers of small ones cannot to some extent find it advantageous to decide now as far as possible how they intend to place their forthcoming crops. An important point to bear in mind is that to get the best results some crops must have plenty of manure worked into the ground immediately preceding their occupying it, while others are more successfully grown where little or no manure has been dug in for a season. Among the former, mention must be made of Peas, Beans, Cauliflowers and Celery; and among the latter, Carrots, Beetroot and some of the green vegetables such as late Brussels Sprouts and Broccoli, will stand the winter better on cold soils without manure.

Cauliflowers wintered in frames, whether pricked out or growing in small pots, will need an occasional examination for the removal of any damped-off leaves, or for a stirring of the soil among those pricked out. Plenty of air should be given upon all favourable occasions. Where there is sufficient room under glass to produce an early crop of Cauliflowers in pots or deep pits and no autumn sowing was done, some seed of a forcing variety should be sown now in pans of light sandy soil and allowed to germinate in gentle warmth. Place the seedlings when up, on a shelf near to the light and prick out when large enough to handle.

The Flower Garden.

Climbing Roses.—Where the thinning and training of these plants were not carried out in the autumn they should receive attention at the earliest opportunity. Remove as much as possible of the old wood so that the healthy young shoots may have every chance of development. Any defects in the supports of such Roses should be seen to at the same time, and planting may take place right through the winter if the weather be open and soil in suitable condition. To those intending planting who have made no selection the following varieties can be recommended, but individual tastes differ so much that probably no two persons would give the same list: American Pillar, single, bright pink; Dorothy Perkins, clear pink; Excelsa, rosy red; Félicité et Perpétue, creamy white; Hiawatha, single, crimson, white eye; Jersey Beauty, single, pale yellow; Lady Godiva, soft flesh pink; Lady Gay, rich rose; Mermaid, single, sulphur yellow; Shower of Gold, yellow; Tea Rambler, salmon pink; and Thalia, white.

Hardy Fruit Garden.

Planting.—We have been fortunate to enjoy suitable weather for this work since it was undertaken during October, and in all probability the majority of it in private establishments is finished unless such work has been on a large scale. If not already done, it would be wise now to mulch all newly planted trees with partly decayed leaves and manure as a protection should severe weather be ahead. Should planting not have been finished, take the first opportunity of an open spell of weather to get it done, and in the meantime make sure that the ground is all in readiness so that there shall be no delay when once planting is put in hand.

Plants Under Glass.

Clivias.—As these plants throw up their flower spikes a slightly warmer house will be beneficial to assist in the full development of the flowers. Should an increase of stock be necessary, choose (after flowering) an old plant or two with some young plantlets around them, remove these carefully and place in pots of suitable dimensions and grow in a warm, moist atmosphere until well established with fresh roots.

Tuberous Begonias.—It is best to sow seeds of these plants early if good results are to be

expected during the summer months. Use a light fine compost and drain the pots or pans thoroughly, afterwards placing them in a warm house for the seeds to germinate successfully.

Lily of the Valley.—To obtain the best results, retarded crowns are necessary, but where these are not used and early spikes are appreciated, they may be had in quite good time by lifting some clumps from the outside supply, and placing them in boxes of light soil in a newly started fruit house or warm greenhouse.

Fruits Under Glass.

Pot Cherries.—As a pot or tub plant the Cherry is one of the most reliable of croppers, and one that requires but little warmth during its early stages—two points which should tend to popularise the above method of culture. Failing an orchard house to accommodate them they may be placed in a Peach house about to be started where a temperature of about 45° will suit both plants. Admit air on all mild days and syringe lightly with tepid water during the warmest part of the day.

Melons.—For early work make a sowing now, placing a couple of seeds in a small 60 size pot filled with nearly all light loam. Place the pots in a propagating pit or where similar warmth may be afforded.

Cucumbers.—Make a sowing likewise of these, for the sooner young plants are in bearing condition the better, so that the winter batch may be grubbed out. Allow the seeds to germinate at a similar heat to the Melons, but use for compost half flaky leaf-soil and half loam.

H. TURNER.

(Gardener to the Duke of Northumberland)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Early Sowings of Seeds.—With the advent of the New Year one's thoughts turn naturally towards the necessary early sowing of certain seeds, but in northern gardens a goodly period must elapse before sowings of even the hardiest kinds can be made in the open ground. In well regulated establishments one of the first duties of the gardener at this time is to prepare his seed order and get it despatched to his seedsman as soon as possible. Extreme care must be exercised in making a suitable selection of the various sorts, as varieties that succeed in one particular district often prove a complete failure when grown in another locality. Deal with firms of repute, and thus avoid many of the disappointments associated with inferior supplies.

Onions.—A sowing of Onions should be made during the ensuing week so that large bulbs may be produced. The soil should be prepared and placed in readiness for the sowing. Use a compost consisting of three-parts fibrous loam, one part leaf-mould and one part manure from a spent Mushroom bed. Pass the compost through a fine sieve and add sufficient sharp sand to render the mixture porous. Use the soil in a moderately dry condition, pressing it firmly into well drained boxes. After sowing cover the seed lightly, firming the surface with a smooth board, water and place in genial warmth. An early variety or Peach house will prove suitable quarters. Cranston's Excelsior and Ailsa Craig are still popular varieties; Austin's Rival is also an excellent sort for northern gardens.

Peas Under Glass.—Where suitable accommodation is available for growing these under glass a sowing may now be made in pots. Sutton's Harbinger is an excellent sort for this purpose, being dwarf in habit and a prolific cropper. Use 6in to 12in pots, filling them three-parts full of old fibrous loam with a light admixture of leaf-mould and sand. Soil saved from Melon pits or Tomato boxes will suit admirably, provided it has been allowed to sweeten in the open for a time. Avoid overcrowding; eight or nine plants to each pot will be ample. A cool temperature with judicious ventilation suits it as nicely, and anything in the nature of forcing as it is generally understood must not be attempted.

Plants Under Glass.

Lilium longiflorum Harrisii.—Pot up more retarded bulbs of this popular Lily for succession and top-dress previous lots that are now growing freely. This Lily, being a stem-rooting variety, responds readily to this treatment, producing flower spikes of remarkable size and beauty.

Amaryllides.—Place a number of these in a warm pit so that they may be had in flower during April. Give a top-dressing of fresh soil to which has been added a sprinkling of Clay's Fertiliser; this will materially strengthen the flower spikes. Spray the bulbs lightly overhead morning and evening, and water carefully at all times, especially until growth is well started.

The Pleasure Grounds.

Shrubs and Trees with Ornamental Bark.—When planting shrubs or trees one should direct one's attention to the various sorts which display their beauty not only during the summer, but are more than attractive during the winter and early spring by reason of the effective colour of their bark. The red and golden barked Willows are especially attractive, particularly so if grouped on the margin of the lake or water garden. The various varieties of Dogwood are also effective. The colour of the plants mentioned may be considerably enhanced by cutting down annually and cultivating them as one year old stems. Other shrubs noticeable for the bright green of their stems are such as *Lycesteria formosa*, *Cytisus* and *Kerria japonica*, while white bark is conspicuous in *Rubus biflorus* ("The White-washed Bramble"), *Salix daphnoides* and *S. pruinosa*, with wax-like bloom on their stems, are most attractive. Silvery stems are very noticeable among the Birches, the white trunk of *Betula alba* being particularly effective, more especially when planted with Scotch Firs or other dark-foliaged conifers for a background. There are many other attractively barked trees and shrubs, so perhaps this note may help to direct attention to their merits.

JAMES McGRAN,

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coatham, Kilmarnock

CONSERVATORY AND GREENHOUSE.

Introductory.—For a good many years before the war choice collections of stove plants had gradually been going out of favour with garden lovers. Many garden owners turned their attention to the cultivation of alpine, hardy herbaceous plants and choice flowering trees and shrubs; indoor gardening in respect of plants and flowers was to a great extent restricted to the growing of supplies for decorative purposes, either for the embellishment of the conservatory or for supplying plants or cut flowers for decorative purposes in the dwelling house. With this style of indoor gardening in vogue, many beautiful and interesting greenhouse plants were soon discarded. I refer chiefly to the many beautiful so-called hard-wooded plants from South Africa and Australia. Apart from Botanic Gardens, such plants are only cultivated to-day by a few commercial establishments, and they only cultivate a few varieties of the more easily grown Ericas and Acacias. The war years, with the lack of skilled cultivators and the high price of fuel, soon led to the abandonment of most collections of stove plants, with the result that at the present time most garden owners devote their plant houses to the cultivation of purely greenhouse subjects that require the minimum of heat; in fact, in many gardens the houses are still devoid of plants, being given over to the cultivation of Tomatoes and Cucumbers. It is sincerely to be hoped that this state of affairs will gradually improve and that choice collections of greenhouse plants may soon be quite common in good gardens. In the meantime the writer will endeavour from week to week to show how the greenhouse and conservatory may be kept more or less gay throughout the year, dealing with plants that may be grown successfully in more or less unheated houses, as well as those plants that require a certain amount of heat during their growing period, but will stand in a lower temperature when in flower. To keep a large conservatory well furnished throughout the year a certain number of growing houses are required, and, as indicated, some of them should be kept at an intermediate temperature during the growing season. For raising quantities of plants from seeds or cuttings a propagating house with some bottom heat at command is essential, but, on the whole, the cost of firing should not be a heavy item.

In restocking empty houses, or where quick results are desired, cultivators should first turn their attention to such plants as can easily be

raised from seeds, and it is surprising the number of useful and beautiful plants that can be raised in this way. Hardy and half-hardy annuals, for example, may be used with excellent effect. The writer well remembers some twenty-five years ago, when many gardeners used to poke fun at the cultivation of such plants for the embellishment of the conservatory at Kew. What was considered strange and trivial then, is a commonplace thing to-day, as witness the many fine examples of such plants that are staged every year at Chelsea and other large shows.

Annuals for greenhouse decoration are generally sown during September in cold frames; in the country such sowings usually give the best results. In the immediate neighbourhood of London such sowings, through lack of light, usually prove failures, the growth being weak and weedy. Here we find it best to defer sowing until early in the New Year. It is true the resulting plants are not so fine as when autumn sown, but with care quite good specimens can be produced, and for anyone who neglected to sow during September, now is a good time to make a start. The plants usually used for this work are *Acroclimium*, *Browallias*, *Clarkias*, *Collinsias*, *Godetias*, *Annual Larkspurs*, *Mignonette*, *Rodanthes*, *Salpiglossis*, *Schizanthus*, *Statice Suworowi*, *S. sinuata* and *Viscarias*. There are, of course, many other annual plants that keep the display up throughout the summer and autumn, but they will be dealt with in due course.

Tuberous-rooted Begonias.—Seed should be sown as soon as possible this month, and with good cultivation a large proportion of the resultant seedlings should make good flowering plants towards the end of summer. The compost for the seed pans should be of a light nature and should include plenty of well decayed leaf soil and sand to keep the whole open. The seed pans should be watered with a fine-rosed can, allowing them to drain well before sowing the fine dust-like seed on the surface. The seed should not be covered with soil, but a piece of glass should be placed on the top of the seed pan and stood in a propagating case with slight bottom heat, 50° to 55° being enough. They should not require any water until they germinate. If water is required, do not give it overhead, but stand the pan in a vessel of water and allow it to soak up. J. Courts.

Royal Botanic Gardens, Kew.

CHRYSANTHEMUMS

Treatment of rooted cuttings.

THE earliest batches of cuttings, inserted at the end of November and during the first half of December, will, before the middle of January, need re-potting. To the experienced cultivator the work is simple enough, but the novice does not find it so. Plants intended to bear large, refined blooms for exhibition require a long season of growth, the naturally late-flowering ones the longest of all. The rooted cuttings of these, inserted singly in small pots, as they generally are, must be shifted to larger ones in the same way as any ordinary plant when it needs re-potting. The rooted cuttings must not be taken direct from the propagating frame and re-potted, but first placed on a shelf or stage and gradually hardened to the temperature of the greenhouse itself.

Should the leaves droop a little, apply clear water if the soil is really dry, otherwise merely spray them, which will have a beneficial effect. In the meantime get ready the various ingredients forming the compost, and clean crocks and pots. The compost should be placed in the greenhouse or shed for a few days prior to its being used; do not use it in a cold state direct from the open air.

We may now closely examine the sketches. Having carefully turned out the young plant, the few crocks (No. 1) should be very gently removed from the ball of soil (No. 2), so that the young roots, not very numerous at this early stage, are not damaged.

No. 3 shows a useful potting stick—cultivators will note its shape, blunt at one end, wedge-shaped at the other. The latter end should be used first

to press down the compost equally all round the roots; the blunt end will then nicely firm the soil without undue pressure, as at this first potting it is inadvisable to make the soil very firm.

The ingredients forming the compost are shown on the bench. No. 4 is the clean crocks required for one pot; No. 5, the good old fibrous loam, 1 bushel; No. 6, coarse, clean sand, a 6in. potful; No. 7, wood-ashes and rotted manure in equal proportions, a 7in. potful; No. 9, sweet leaf-soil, half a bushel. Of course, charcoal may be difficult to obtain; if possible, however, about half a dozen small pieces, as shown at No. 8, should be mixed with the rough compost placed on the crocks. No. 10 shows how the crocks should be placed; No. 11, the small quantity of rough compost on

POTTING UP ROOTED CHRYSANTHEMUMS.

which the ball of soil and roots of plant (No. 12) are placed; then the work of potting is completed by filling up and gently firming the soil placed in position all round the roots to the level shown. Mix the ingredients thoroughly.

The young plants must afterwards be placed on a stage or shelf about 18ins. from the roof glass. Spray lightly with tepid water and shade from strong sunshine. Be careful, however, when applying water not to create a continuously soaked condition of the soil. Do not shade at all when new roots are beginning to permeate the new soil. Continue the propagation of early-flowering varieties for exhibition; also freely insert cuttings of the numerous single flowered and decorative sorts.

GEORGE GARNER.

ORCHARD

GARDEN

WOODLAND

THE DOG: MAN'S FIRMEST FRIEND.

How to choose and care for him, by A. CROFTON SMITH. A copy of this helpful booklet on the housing, breeding, feeding and care of dogs will be sent post free on receipt of 1ld addressed to The Manager, "COUNTRY LIFE," LTD., 20 Tavistock Street, Covent Garden, W.C.2.

THE announcement, made in our Correspondence pages, that Messrs. de Graaff, the justly famous Netherlands firm of nurserymen, have purchased land for a bulb farm in South Lincolnshire gives food for thought. Messrs. de Graaff, it may be anticipated, will employ to greater or larger extent British labour; they will certainly have to contribute their quota to British rates and taxes, so that the British bulb industry has no special need to fear their competition. It is surely worthy of note that while one big Dutch grower has been attempting to convince himself and other people that the British-grown bulb is fast dying a natural death, another even more important firm should have thought it worth while to establish a nursery here. Let us once obtain a go-ahead British Bulb Growers' Association and there will soon be room for immense expansion in the industry.

An International Exhibition?—It is now almost ten years since the great International Horticultural Exhibition was held at Chelsea, and it would surely be well if the powers-that-be were to take in hand the organisation of another one. It would not now be possible to arrange such a show for the coming year; indeed, it is high time the matter were taken in hand for an exhibition in 1923. Now that the long awaited International Iris Conference has turned out to be a French function, it behoves British horticulture to look to its laurels. The four years which will, in 1923, have elapsed since the close of hostilities in the great war, should have done much to restore nurseries generally to something approaching pre-war condition.

Care at Planting Time.

—The precautions advocated on page 17 with trees and shrubs newly arrived from the nursery may seem obvious, but experience has shown that they are, too often, not carried out in practice. Much loss of valuable plants which is attributed by the purchaser to insufficient transplanting or bad packing by the nurseryman is, in fact, directly occasioned by want of ordinary care in the interval between receipt and planting. Exposure to a bleak wind for even a few minutes will do

immense damage to the living roots of plants; to leave them exposed, as one often sees them, for hours—aye, even for days and weeks—is but to invite disaster. Where extensive planting is to be done, unskilled labour is often drawn upon. It behoves those in charge to be particularly vigilant lest grave damage come about through ignorance.

The Winter-Flowering Heath.—The favoured few whose gardens lie close to those coasts where break the waters of the Atlantic have usually many flowers to select from outdoors at this season. Even in Midland gardens it often happens that Violets, Primroses and Polyanthes may be gathered in January; but one always feels that they are stray flowers appearing out of season. One cannot think thus of *Erica darleyensis*, which usually commences to flower in November and continues the winter through. The very amateur gardener—perhaps, it would be truer to say the real novice—almost invariably purchases all kinds of plants in flower. He finds, in course of time, that this is not precisely the right time to buy and so often concludes that it is impossible to transplant plants in bloom. Because of this conviction, some gardeners refuse to take delivery of *E. darleyensis* in winter or spring. This is an entirely mistaken idea, as this Heath and the

other early flowering kinds may be moved in spring, autumn or winter with the greatest ease. The illustration depicts the Darley Dale Heath massed in a bed, but it can be used most effectively among occasional boulders arranged to suggest moorland effect. If a double season of flower is desired, it may be interplanted with the Cornish Heath (*Erica vagans*). Bluebells or Squills may, in any case, be planted between. Like *Erica carnea*, it may be used as a formal path edging. So employed it may be kept almost as neat and tidy as Box and still bloom freely each season. *Erica darleyensis*, is, it must be admitted, a common enough plant, but it is uncommonly useful.

Do Not Forget to include, when making out the flower seed order, a few packets of that charming hardy annual the Sweet Sultan, so charming in itself and so valuable for cut flower. Let no one despise the annual *Gypsophila* (*G. elegans*). It lacks, it is true, some of the feathery lightness of the perennial, *G. paniculata*, but it can be induced to flower at any period of summer and autumn, and therein lies its value. Those who have not done so hitherto can confidently be recommended to try that slender-habited hardy annual *Brachycome iberidifolia* (Swan River Daisy). The cactus or star-flowered forms are particularly charming. These, like the now too

seldom seen *Rhodantes*, make neat and pretty pot plants. No annual probably is more neglected or maltreated than *Phlox Drummondii*. The plant is quick growing in the early stages as well as a gross feeder, so that it is only too easy to produce stunted, useless plants. It makes but little fibrous root, and so removes unsatisfactorily from boxes. Grown right on, however, and planted out from 3in. pots into beds of rich soil, this is among the most effective bedding-out plants. Seed may now be obtained in separate colours, which is a great advantage. These annual Phloxes are too little used for cut-flower purposes. Many readers will, no doubt, wish to try the so-called "Blue Shirley" Poppies, of which "Somers" wrote so convincingly a while ago. Their colouring, it may be noted, sorts oddly with that of the true Shirleys, so that they should be kept apart.

JANUARY FLOWER ON *ERICA DARLEYENSIS*.

THE ALPINE HOUSE

A further list of suitable plants with notes on the proper composts.

OTHER suitable plants for the alpine house include the *Ethionemas*, all species and varieties from the compact and not too easy *juvunda* (*Iberis juvunda*) and the quietly beautiful *coridifolium* to the brilliant new Warley Hybrid. Then there is the multitude of alpine and dwarf *Campanulas* from which to make a selection. That quaintest of species, *C. Zoysii*, so beloved of slugs, must first have mention, but the tiny *Waldsteiniana* and the uncommon *Raineri* may have room found for them in the tiniest of glass houses. Easy though they be, *Portenschlagiana* (*muralis*), *pusilla* and varieties and *garganica* and its varieties are all worthy; while if space allow, the forms of *turbinata* and even *carpatica* may well be included. The pretty hybrid *haylodgensis* is very desirable, and there is a specially beautiful double form. The double form of our common Harebell, *C. rotundifolia* fl-pl. is beautiful and interesting; so are *valdensis*, *Stansfieldi* and *Steveni nana*.

Of the *Cranesbills*, the best for our purpose, owing to their "finish" and neatness of growth, are *Erodium amannum* and *Geranium Traversii*, the last named a very welcome New Zealander. *Geranium sanguineum*, the Bloody *Cranesbill* of our own hillsides, is beautiful and effective where space can be spared for it.

Of the *Geums* the only "indispensable" is the too uncommon *reptans*, but the quietly pleasing *rivale* Leonard's variety may be considered worth a place.

Haberlea rhodopensis and *Ramondias*—*pyrenaica*, at all events—we must have. The beautiful pure white form is exquisite under glass. Care must be taken to keep these free from red spider and to turn them out into cooler quarters immediately after flowering.

The trailing *Veronicas* are too coarse for the alpine house, but some of the tiny "shrubbies" should find a place. Such are *Catarracta*, *sah-cornoides*, *cupressoides*, *epaeridea* and, where possible, the larger *Hulkeana*.

There are several quite small species of *Potentilla*, but none to approach the beautiful *nitida*. This should have a place with the beautiful pure white form if possible.

When writing of *Primulas*, the charming *Julize* should have been included. There is nothing better for our purpose. There are now several rose to crimson hybrids between this and our native *Primrose* (*P. acaulis*). Some of these would here be seen to advantage, and their foliage bears inspection. Of *Primula rosea* it is scarcely necessary to write. Most people would wish to include it.

Of the genus *Lychnis* *L. Lagasce* should be included, while the quaint little *L. alpina*, so beloved of bees, may be grown if desired. It should be renewed periodically from seed. Of *Silenes*, *alpestris* and *Schafta* should find a place.

Of *Forget-me-nots* *Welwitschii* is too rampant under glass, but space will assuredly be found for the wonderful *Ruth Fischer*, if not for the tiny *Rehsteineri*.

The alpine house is the only really fitting place for the hardy *Sarracenias*. Here, in a compost largely composed of sphagnum, they will flourish.

Of the *Arenarias*, all are beautiful, but, despite its freedom of growth, *A. montana* is too lovely to be omitted.

Among *Woodruffs* the tiny *Asperula Gussonii* and the wee pink *suberosa* are charming. Of the rhizomatous *Anemones* there are several beautiful

woodland-compost-loving forms of *A. nemorosa*. Both *Robinsoniana* and the newer *Alleni* are delightful, so is *Blue Bonnet*. The chalk-loving *Pasque Flower* (*A. Pulsatilla*) is worthy of the closest inspection, so particularly at home here.

THE VERY BEAUTIFUL LILAC-PINK OXALIS ADENOPHYLLA.

Halleri is a very beautiful variety, and there is a charming pure white form. Little colonies of *A. blanda* will, in early spring, be very welcome.

None too hardy outdoors, those two tiny *Snapdragons*, *Antirrhinum Asarina* and *A. glutinosum*, will here be at home. So will the lime-loving *Douglasia* (*Androsace*) *vitaliana*, which, to flower freely, needs abundant sunshine.

Of the forms of *Alyssum*, *montanum* and *spinosum* are most suitable. There is a pale pink form of the last—*A. spinosum roseum*.

The quaint little hardy *Calceolaria polyrrhiza* should have a place, so should the gorgeous heat-loving *Calandrinia umbellata*, which is not a long-lived plant. It is, however, easily raised from seed.

For a cool corner a little patch of *Cornus canadensis* would be charming, while contrast may well be obtained from the bronzy rosettes of *Corydalis cheilanthifolia*.

All the hardy *Cyclamens* are suitable and easy if kept out of full sunlight and given a light, well drained compost containing mortar-rubble. Also cool loving are the numerous *Shooting Stars* (*Dodecatheon*).

Of trailers, *Linaria pallida* is one of the most valuable, but the tiny *Arenarias balearica* and *caespitosa*, *Hernaria glabra* and *Hutchinsia alpina* are all valuable, as is the bronze-leaved *Epilobium Hectori*. Very different is the procumbent *E. obcordatum*; it is, however, quite effective. *Epilobium* naturally brings to mind those herbaceous *Berberids* the *Epimediums*, which may readily be brought to flower early under glass. The best species is unquestionably *niveum*; there is a beautiful pink variety *E. n. roseum*. Another beautiful species is *E. sulphureum*.

Of the *Hypericums* *H. reptans* is alone worth house room. This, everyone is agreed, is a charming species.

Of the *Mertensias*, most species are too coarse for the purpose in view, but this does not apply to the charming *M. primuloides*.

BELOVED OF ALL—EVEN THE SLUGS!—THE MINUTE CAMPANULA ZOYSII.

Coming now to the Wood-sorrels, those charming exotics, *Oxalis enneaphylla* and *O. adenophylla*, are specially suitable, so is the beautiful but little-known winter-flowering *O. lobata*. This has yellow flowers.

The alpine house is a happy place in which to grow some of the smaller and more beautiful *Pentstemon* species, for this is a genus which contains, among a deal of worthless rubbish, a few really beautiful alpine species. One of the most beautiful is *P. coruleus*, which, also known as *P. angustifolius*, is a neat plant which carries its lavender-blue flower-spikes erect, in which it differs widely from *P. alpinus*, of which, however, the colour approaches more nearly a true azure blue. A quaint scarlet-flowered species is *P. Newberryi*, which should not, of course, be confused with the hybrid *Newbury Gem*, to which it is in no way related. Neatest and most truly alpine of all is the now generally familiar though not widely grown *P. Davidsoni*. Its flowers are rather startling in colour owing to the touch of blue which enlivens their brilliant red. Plants in pots and pans, however, can always be arranged to prevent colour clashes.

Of the alpine *Violas*, *V. gracilis* is indispensable and our native *V. lutea* very lovely.

There are, of course, numbers of excellent plants which have not been mentioned in the foregoing notes, and much will depend in making a selection upon the personal tastes and inclinations of the would-be grower, his facilities for growing alpine outdoors and the aspect and character of the house or houses to be allotted to them. Some will wish to grow species reputed to be difficult, such as *Eritrichium nanum* or *Cyananthus lobatus*, though this last is easy enough under glass. Others, again, will try to establish collected alpine plants. These are not always satisfactory from the point of view of flower, however. *Silene acaulis*, to take but one instance, is in our lowlands poor in colour, whether grown under glass or outdoors; not too free-flowering even in its native mountains, it is usually over-shy in cultivation.

Important enough in the rock garden, proper composts are all important under glass. Plants of the damp alpine pastures are best accommodated in a compost, consisting largely of sphagnum, such as was described in the article on seed raising in our issue of December 24th last. Plants which require lime may have the essential ingredient

CAMPANULA GARGANICA HIRSUTA AND ITS WHITE VARIETY (ILLUSTRATED) DISPLAY THEIR BEAUTIFUL FOLIAGE TO ADVANTAGE UNDER GLASS.

provided in the form of broken (not powdered) limestone, old mortar rubble or broken oyster shells. Small washed gravel is very useful for equalising the supply of moisture. In addition to its use in actual compost, pans of drought-hating plants may be plunged in it on the staging. In the case of "miffy" plants, such as the various species of *Cyananthus*, which need ample moisture, but easily damp off in the lowlands, a liberal admixture of small coke will be found a considerable safeguard. Two ingredients the writer has found much overdone for alpinists in pans. They are peat and sand. The former should never be used alone, and not at all except for peat-loving plants, and sand as a separate ingredient should be banned. It is usually employed

with the idea of making the compost porous. Its effect is, of course, the reverse. For plants which outdoors flourish on the "moraine," a moraine compost should be employed under glass. This should consist of at least three parts of suitable ballast, fine gravel, broken potsherds and small coke to one part of soil compost, which should in the main consist of clean fibrous loam with additions of peat, leaf-mould or mortar rubble to meet the special requirements of the individual species.

RIVIERA NOTES

DECEMBER has proved, as usual, one of the finest months of the year. It began well with two days of good rain, but the drought has not been broken since, so that much watering is necessary to keep the garden going. Fragrance is, I think, the note of this month, for *Chimonanthus fragrans*, *Buddleia auriculata* and *Freylinia cecyloides* are all in fullest flower and fill the still and sunny air with their scent that lingers in a way that no other season permits. No garden on this coast should be without these delightful and hardy shrubs.

Dimorphothea aurantiaca makes a specially bright patch of colour on a sunny terrace also. It is an annual that is not planted as freely as it deserves, and serves as a useful contrast to the Chinese *Prioules*.

The scarlet-flowering *Aloes* are among the succulents that enjoy sunshine and drought, and are already in flower earlier than usual, and the trails of pink Ivy-leaved *Geranium* are also prettier and more full of flower than usual.

I never saw *Bignonia venusta* in better flower than it is now, spite of last year's cruel December frost.

Heliotropes have suffered much from the drought following on that last year's frost and

OXALIS LOBATA PRODUCES ITS FLOWERS OF DEEPEST GOLD IN LATE AUTUMN.

are much less beautiful than usual. *Lopèzia miniata* has, on the other hand, enjoyed the season and is a mass of its dainty flowers.

There is at last a movement of protest against the poverty and banality of the public gardens at Nice and elsewhere. Journalists and French gardeners are beginning to realise that Palms and grass, with bedded out little parterres of *Primulas*, *Pansies*, *Cyclamen* and the like, need some setting of *Cypresses*, *Carob Trees*, *Umbrella Pines* and other indigenous trees; and the *Orange* and *Lemon* and *Olive tree* are not to be despised because they are so common in the countryside.

There is a comparative scarcity of "*Mimosa*" this year, as so many perished in that bitter frozen wind last year; and *Acacia dealbata* will reign alone this season in the markets.

Iris stylosa, which is reported to be blooming so freely in England, is hardly yet able to make a presentable show, the flowers are so short-stalked and poor owing to the drought. I have no doubt that various early forms of *Narcissus tazetta* will be in bloom in some Northern gardens long before they dare to grow here!—a curious inversion of the ordinary state of things. May the new year grant us good rains! E. H. WOODALL.

The Cult of the Tuberous Begonia

Its origin and developments, propagation and culture.

LOOK at the tuberous-rooted *Begonia* as we see it to-day at some great London exhibition! Proud and serene, conscious of its incomparable beauty and magnificence, in both single and double forms, embracing a range of colour that few flowers can excel. These magnificent flowers have been achieved by patient cross fertilisation and selection, by constant intermarriage among but a handful of species, all of which, by the way, save one, bear red flowers. The first of these species was only introduced into England as comparatively recently as 1857. A marvellous story truly, and a flower before which we can but bow our heads in amazement.

The year 1857 saw the introduction of *Begonia boliviensis*, a species with small scarlet flowers which is seldom—if ever—seen nowadays, followed eight years later by the yellow-blossomed *B. Pearcei*. These, no doubt, were hailed as wonderful introductions by the garden lovers of the time. They proved to be the founders of that gorgeous family which is so appreciated to-day. Both these were natives of Bolivia, but the next introduction—*B. roseiflora*, introduced in 1867—came from the Andes of Peru. In the same year, the orange scarlet *B. Veitchii* was also introduced, again from the highlands of Peru. Then came a long pause, for it was not until ten years later, in 1876, that the last species—*B. Davisii*—in our chain of parentage appeared before the public.

From that time a continuous improvement has been maintained right down to the present day: one triumphant succession of increasing size of flower, vigour of foliage and hardiness of constitution. At first these plants were regarded as demanding stove treatment to secure success, and men's hair would have stood upright at the mere suggestion of planting them out in the open for summer bedding! Wonderful as all this is—for, in effect, an entirely new plant has been created—I have often asked myself the question, "Are all the possibilities behind us?" Is the modern tuberous *Begonia* still capable of fertilisation by one or another of its forebears; and if so, what would be the effect of harking back to one of the original parents? Only last year seed was offered for the first time of a new strain, known as the *Narcissus-flowered*. I have yet to see this, but it is described as "a remarkable new race of tuberous rooted *Begonias*, producing flowers resembling in shape a double trumpet *Daffodil*, the inner petals being joined into a large double corona, with petals elegantly waved and frilled at margin; in colour, the flowers range from light to dark yellow, orange, buff, blush, rose, dark red and scarlet." This is but another step on the way, to show that the end is not yet; and, provided our "new" plants and strains still remain capable of fertilisation by one

or another of the older parents, new and still more striking breaks may still be procured by retracing part of the road and re-treading it. There is a tremendous fascination in all this speculation and

warm, the batches of plants will flower within a week of each other.

Very fine soil is essential, as the seed itself is so very minute. Shallow wood boxes are excellent receptacles for the purpose of sowing seeds where quantities are to be raised, but, where possible, seed pans are better. In either case, plenty of crocking material should be used to ensure effective drainage. To keep this from becoming choked up by the finer earth, a layer of rougher soil or moss should be placed over this. It is only the top in. of compost that needs to be very fine, and this should be made quite firm and very smooth and level. Water through a fine-rosed can and then set aside for a few hours to drain before sowing. This sowing is a ticklish business, for, while it is desirable to sow thinly enough, so that the young plants will not require pricking off until of some size, this is, owing to the minuteness of the grains, by no means easy of accomplishment. The old time-honoured dodge of mixing with a rather larger bulk of very fine silver sand facilitates thin distribution as well as anything. Sowing completed, the vessels containing the seed should be covered with a sheet of dark paper and a pane of glass, for

THE LATEST TYPE OF BEGONIA, SUTTON'S DUPLEX, CORRESPONDS ROUGHLY TO THE PÆONY-FLOWERED SECTION IN DAHLIAS, BUT HAS MORE REFINEMENT AND FINISH.

experiment, and I, for one, certainly mean to investigate along the lines I have indicated.

Culturally, the grower's thoughts turn at the present time to seed sowing; that is the first operation of the year and the sooner it is done now—provided that adequate heat can be maintained—the better. Early sowing means earlier flowering with a correspondingly longer season of flower harvest in summer and autumn; but if a sufficient temperature cannot be procured thus early in the year, sowing can be delayed until the end of February or early in March, and the flowering plants still be obtained by the middle of August. Nothing is gained by merely sowing the seed and persuading it to germinate, unless one can keep the youngsters growing; better defer it for two months even, for I have proved that a couple of sowings may be made six weeks apart and yet, unless the earlier sowing was kept additionally

one cannot attempt to cover the seeds at all with soil, and the paper serves to ensure the darkness that is essential to germination. Reverse the glass daily to disperse the inevitable condensation and do not water until the surface requires it. It must then be done from below, as it is impossible to water from above without disturbing the wee seeds, possibly when just at the point of germination. Lower the pans into a vessel of tepid water so that this rises to half their depth and wait until it has percolated through the surface; then lift out, drain and replace the glass as before. A temperature of 60° to 70° is sufficient, and, for soil, I prefer a good yellow loam sterilised by baking, to which one part of sand has been added. Leaf mould, that is used at a later period of their culture, should be tabooed as it encourages the growth of green moss, that overruns the seedlings and checks their growth. For the same reason, use

main water for moistening the soil when this is required; that in the under-stage tanks very often contains the spores of various mosses that begin to grow as soon as they fall upon the kindly soil. Germination should be followed by the entire removal of the paper and the gradual removal of the glass, and then regular watering, so as to keep the soil evenly moist, is all that will be required until the first pricking off is done. This needs extreme care, for nothing is more brittle than a baby Begonia. To prick out thinly in fresh pans or boxes is the best method, for the largest leaves will not at this time be larger than a tack head. They should now be grown on until the largest leaf is about the size of a penny, before finally potting in separate pots.

Let us leave these at this stage and turn our attention to another phase—starting the tubers. It does not matter whether the ultimate destination of these is beds outdoors or culture in pots for procedure is the same. Take out the tubers from their storage place and carefully look them over, to make sure that they are in perfectly sound condition. Any that show signs of decay should be examined to see if this has spread through the whole tuber or if a portion only is affected. If the latter, cut this out with a sharp knife and powder the cut surface with finely crushed charcoal. Shallow wooden trays may be employed for starting and, after many experiments, I have found nothing that is more satisfactory all round than pure leaf mould. Some growers, however, prefer coconut fibre. Fill the boxes to the top with whichever is selected, firm slightly and press the tubers into it, so that they are just level with the surface, but not covered. A temperature of 55° to 65° is ample to start these growing freely, a process that is facilitated by damping down and sprinkling the surface through a fine-rosed can. Do not get the leaf soil over-wet, however, and note that the surface of the tuber is slightly concave; water if allowed to collect in this cavity will rot the young shoots. Keep in a good light and as soon as well started, pot off singly those which it is desired to grow in the conservatory. Plants that it is intended to grow in the open should be allowed a little more space in the boxes and can then often be grown on more slowly, hardened off and planted direct from the boxes into the beds without the need for potting at all. A good compost, both for young seedlings and older tubers that are to be grown in pots is a *sine qua non*, and one will find it hard to beat one of three parts fibrous yellow loam and two parts of leaf mould and one part each of decayed manure and silver sand. The size of the pots must, of course, vary with the size of the tuber—a question of age—1 ins. to 2 ins. all round being sufficient margin. Personally, I am adverse to very large tubers; it is in the second and third year that the grandest flowers are produced, and after that time the large tubers should be used perhaps for bedding, while other younger and more vigorous plants from seed should replace them under glass. Until buds form, a moist atmosphere promotes quick growth, and the staging, etc., between the pots may be syringed freely with advantage; but once buds commence to form, a drier condition of the atmosphere is imperative or they will drop these buds "wholesale." A certain amount of shading from exceedingly bright sunlight must, in summer, be arranged for, though it is an error to shade the tuberous Begonia too heavily. Break the light with a thin screening only; a thin blind is the best method as this can be run up and down as required. Watering is the chief item that now needs attention, for the more even the state of moisture in which the soil can be kept, the better the flowers and buds expand. Over-watering causes a rush of sap to rise in the stems and forces the buds off at the top; on the

other hand, drought reduces the flow of sap and the buds fall from that cause too. When water is needed, enough should be given to soak the whole ball right through, then no more until the surface begins to dry. The circulation of air, too, must be perfect; a light and buoyant state of the atmosphere is as important as even moisture at the roots. Feeding, too, is an important item, for the Begonia is a very gross feeding plant, capable of absorbing large quantities of plant food, upon the principle of "weak and often." Liquid manure, made from animal droppings, chemical fertilisers, nitrate of soda, soot water, can all be employed in turn, varying these as much as possible, using them really weak and always after watering first with plain water so as not to burn the roots.

Towards autumn is a critical period, for many tubers are lost annually owing to imperfect ripening. The ripening off should be done as slowly as possible. As the foliage yellows reduce the supply of water—but not suddenly—and on no account separate the stem from the tuber until it falls away naturally. Once completely dried, lay the pots on their sides in a frostproof place with the tubers in them, or, if they must be taken out, clean them and store in dry earth until spring. Started tubers which are to be planted out in the open, should be prepared for this by a very thorough hardening-off process, transferring first from the greenhouse to a cold pit, which must be kept closed and matted up at night. Then gradually admit air until the first week in June, by which time they should be capable of standing entirely exposed both night and day, ready for planting out.

A sunny position is better for this than shade and the ground should have been very thoroughly prepared and manured some time previously. A mulch of old manure, a week or two after planting, is a useful aid to keeping the roots in that equable state of moisture that is so conducive to fine foliage and free flowering. Few things can be more vivid

—from the point of view of colour—than these inimitable flowers, especially the singles, though the smaller doubles (as used at Hampton Court, in association with *Leucophyta Brownii*) are capable of gorgeous effects when confined to one colour alone. When the first severe frost comes the tops will be cut back to the ground level and the tubers should then be lifted and laid out in a frostproof place to dry. When the soil has become so dry that it all powders off the tuber, the skin of these will have toughened sufficiently to enable them to be cleaned and stored away for the winter.

Should one have a special variety that one wishes to propagate true to type, this cannot be done by seed, and cuttings must be taken in summer. These are not easy to root, but careful handling will ensure good results. Cuttings are formed from the side shoots, which must be broken out at the point at which they spring from the main stem. It is useless to sever them just beneath a joint in the usual way, for when this is done—although they form roots freely—the tubers never swell to a greater circumference than that of the stem at the time of rooting; whereas those broken out close to the point at which they broke from the main stem will expand in the normal way.

Allow the plants to become rather dry for a day or two before snapping out the cuttings, as this reduces the sap flow and hastens rooting. Very sandy soil should be used for inserting, taking care that the base rests upon a little heap of sand, and keep the foliage fresh by placing in a closed propagating frame. Very moderate supplies of water only should be given, and when growth recommences from the tip, take them up and pot separately, growing on exactly the same as seedling plants. Cuttings can be taken any time from the period when the side branches are sufficiently long until August—though the earlier it can be done the better, as a fine tuber is thus obtained before autumn stays further growth. H. W. C.-W.

PRECAUTIONS IN PLANTING

Many trees and shrubs are, each season, lost through neglect of simple precautions at planting time.

CHRISTMAS in this country seems to be a real dividing line for work in gardens. We, most of us, speak of work to be done before Christmas and work to be begun in the New Year. Many like to do the bulk of their planting operations in the autumn, and, indeed, in light, dry soils it is the safest time for most shrubs, at any rate. The ground, if work is begun in early autumn, is warm and, given moisture, which in most years comes with great regularity, encourages quick root action, which is so desirable in all transplanting. As the growth of a plant matures in autumn, the energy of growth goes into the roots and this is practically automatic.

Root growth is undoubtedly at its maximum at this period. In hot, dry soils the autumn establishment of newly planted specimens is very valuable and saves many anxious moments during the following spring and summer. It is wonderful how small an amount of new root in a plant will ensure safety.

On the other hand, many favour spring planting, and in heavy soils it is sometimes impossible to plant until the soil has been weathered and breaks up into a fine friable condition. It is a good time to plant just as things are moving from the dormant condition, and many evergreens move without much check when they are actually commencing their growth. The writer has moved

Conifers, such as Austrian and Corsican Pines, Douglas and other Firs when they had made 2 ins. or 3 ins. of growth in late May and June, with great success.

In a nursery the time to move and plant up stuff of all kinds is when an opportunity can be found to do it, more than choosing the right moment, and given that plants are not too badly rooted, it is extraordinary how little loss is incurred. But this is the important point: Insist on good roots. One might paraphrase an old saying: "Take care of the roots and the tops will take care of themselves." In choosing plants from a nursery do not be led away by plants which look in full vigour of growth, with heavy foliage and long leading shoots. One may depend that with a gross appearance of growth on top there must be a corresponding vigour of roots, and once big roots appear the difficulty of successful transplanting is increased. Look rather for plants with short leading shoots, comparative thinness of foliage and an air of thriftiness generally. This to an experienced eye is easy to see and cannot be mistaken, by one who knows, for bad health.

Another point which is, perhaps overlooked is the difference of moving plants in one's own garden to purchasing from a nursery and receiving the consignment three or four days later, after having been handled several times, and that

not too carefully. In addition, the weather may be dry with a keen, evaporating wind. In the first case the plants can be lifted with a large ball of earth, much larger than an ordinary nursery plant can carry, and are taken from one position to another in a few moments, and the roots are scarcely exposed when they are again covered; so handled there is little cause for failure. In the other case the plants have to be taken first from the nursery to the packing sheds, there to be packed as carefully as possible and often with good balls of earth attached. They then are loaded in a van, transferred to the railway authorities, who handle them again two or three times, and, on arrival, there is a further process of unloading and loading till in the purchaser's hands. Even then their troubles are not over. Packing has to be removed, and when finally planted, it is seldom that much soil remains round the roots, and all this after perhaps three or four days out of ground.

There is a big difference in these points, and it is not always the nurseryman's fault when losses are incurred. This comparison of home and imported plants is made with a view to showing that although the season may be right, there are other reasons for failures, and plants so received should be given every possible help when planting.

Although there is a best time for everything, it is not always possible to avail oneself of it; but we are so fortunate in our climate that it is not of such great consequence after all, and we can go ahead with planting operations from October to May without incurring any great risks. Of course, from time to time we are held up by excess of rain or, perhaps, frost, although in recent years we have not been affected much in this respect. In the winter of 1895 ground operations were held up by the great frost for about eleven weeks. The frost that year penetrated to a depth of 2ft., and it took nearly three weeks of warm, sunny weather to thaw it out after the frost had ceased. Planting operations that season were much restricted. Such a winter may occur again, and after so severe a drought as we have gone through the last twelve months, and taking into consideration the particular effect of it on last spring's planting it will be well to take advantage of the right moment as far as may practically be possible.

Another important point is to look after plants properly immediately on arrival. The writer has from time to time seen a truck load or more of trees lying about all over the place, exposed to the four winds of heaven, frequently with roots exposed. The planting gang cannot plant every one at the same moment, and it seems advisable that a good system of receiving stuff should be adopted. For instance, upon arrival, verify first the contents of the package or truck and check it with the original order and delivery note. Make sure the plants are not dry, or if they should be, have them moistened. Choose a sheltered spot for unloading, and if any quantity has to be dealt with, have them laid out in their various kinds, so that each may be easily taken out as wanted, and cover the roots with litter or loose soil. When each plant is allocated to a position it is a then simple matter to pull out what is wanted. Never plant in a dry condition, but first either thoroughly soak the root or ball of a plant or water it in before finally filling in the hole with soil. These precautions would save many disappointments and many grumbles.

When finally the plants have been covered in, take care the ground is well trodden, and in light soils it cannot be trodden too firmly. The larger plants will require to be staked or supported so that they cannot blow about. Nothing is

worse for newly planted trees than to have a continual backwards and forwards movement which by degrees produces a considerable space

round the stem of the tree just where it joins the soil. Any tree loose at the "collar" like this will have difficulty in surviving. F. G. W.

THE IMPORTANCE OF CONTRAST IN TREE AND SHRUB PLANTING

WHEN planting a shrubbery or belt of trees, contrast of habit and foliage should be borne in mind as equally important as variety and contrast in flower.

In the case of deciduous trees, contrast in arrangement of the naked stems and variety in the colouring and appearance of the bark should also be provided for.

Contrast in foliage is not easily illustrated photographically, but the exotic pale green leafage of the Tree of Heaven (*Ailanthus glandulosa*), even in the picture, forms a remarkably effective contrast to the more rigid habit of the surrounding hard-wood trees.

The other picture illustrates, not ineffectively, a shrubbery border in which diversity of habit and of foliage have alike been exploited to good effect.

It may not be inappropriate to consider a few particular instances where such contrast has been found effective. Silver Birches and Scotch Firs will probably suggest themselves to everyone as representing an ideal in trees. Hardly less effective, however, in association are the Austrian Pine and Lime. The false Acacia (*Robinia Pseudacacia*) contrasts effectively with the round-headed Quickthorns, particularly the single scarlet variety (*Crataegus Oxycantha punicea*). The gold or silver variegated Negundas (forms of *Acer Negundo*) are often associated with the Purple Plum (*Prunus pissardii*), but here the contrast is almost entirely one of colour. A bold but irregular grouping of these Negundas on soil which suits them will look very beautiful against a background of Purple Beech. Reverting again to plantation effects, one of the most effective contrasts, albeit a seasonal

one, is provided by the tender green of the new foliage of the Larch against the black-green of dark Pine or Spruce.

Their value as contrast justifies the inclusion in mixed shrubberies of some of the upright Cypresses, Junipers and Yews. Their columnar habit and characteristic, if varied, foliage contrast wonderfully with round-headed trees and bushes, such as those of the Thorn, Lilac or Broom, or with spreading trees like the Laburnum or some of the ornamental Pyruses. Where space allows, the Cypresses, particularly the *Lawsoniana* forms, are inferior in general appearance, and especially inferior for the particular purpose in view, to many of the Firs. No tree of aspiring habit can excel in beauty a well grown and reasonably mature Spruce. The Oriental Spruce (*Picea orientalis*) is particularly fine.

Plants somewhat tabular, such as *Cotoneasters horizontalis* and *adpressa*, *Viburnum tomentosum plicatum*, *Taxus Dovastoni*, and many of the dwarf Junipers, especially the beautiful *tamariscifolia*, are particularly useful for the contrast they afford to shrubs of more usual habit.

The value of the various coloured barks for producing winter effects was touched upon under "Gardening of the Week" in last week's issue. It may be noted in passing, however, that a very pleasing contrast alike of habit of growth and bark coloration is provided by associating *Cornus sanguinea* and *Kerria japonica simplex*. The latter shrub is too often neglected in favour of the grosser habited double-flowered form which, though effective enough when massed, has little grace of spray or beauty in the individual flowers. The cret habit and tawny bark of many of the *Deutzias* make them invaluable in the shrubbery.

A WELL ARRANGED SHRUBBERY BORDER. NOTE THE CONTRAST IN HABIT AND FOLIAGE COLOUR.

The same may be said of the stronger-growing varieties of Philadelphia.

Rhododendrons and Lilacs have the natural contrast afforded by the tough dark foliage of the evergreens and the lighter, more flimsy leaves

Further contrast in the shrubbery can be well afforded by the introduction of bold masses of hardy Heaths or of herbaceous plants of sorts. This point has often been touched upon in THE GARDEN, so that there is no need to labour it, but

the value of groups of coloured Primroses—perhaps blue ones if these are admired—Polyanthus, or, better still, coloured Cowslips, cannot be over-estimated.

If the shrubbery is of really effective dimensions and in not too bleak a situation, a few kinds of hardy Bamboos may be introduced, always remembering that, in their place, the small sorts are as effective as the larger growers. Even in a narrow shrubbery room can be found for, at any rate, a few clumps of Yuccas, though they be only filamentosa or flaccida. Then, too, there are the Pampas Grasses with autumn plumes of silver or pink, as personal taste may select. It is a pity, though, that the pink ones do not retain their colour longer; while where these would prove too large there is quite a variety of Miscanthus (Eulalia) to fall back upon.

Some people have a natural gift for forming garden pictures; to some it seems denied, but it is very doubtful whether the "gift" goes really much further than careful observation applied

to practice. Whether by early training or by inheritance, some folk are undoubtedly much more observant than others, but observation is a part of education not difficult to acquire. It is undoubtedly an invaluable part of the gardener's mental equipment.

AILANTHUS GLANDULOSA IN A MIXED PLANTATION.

proper to a deciduous bush; but, somewhat alike in their round-headed habit of growth, either may be used to contrast with shrubs naturally fountain-shaped—that is, with arching branches—such as most Berberises, but especially stenophylla and many Brooms.

THE BUSH APPLE TREE

Its training and pruning.

IN your issue of December 14, page 656, Mr. A. H. Pearson takes exception to some details of training and pruning I recommended in an article on page 621. In the first paragraph of his notes he states that I "write from an amateur's point of view." I do not know whether or not this is intended as a compliment, but I do know that if our gardening journals were to lose the support of their amateur writers they would be shorn of many of their most attractive and interesting attributes. However, I am content to write as I have worked—simply as a gardener; I neither claim nor wish for a higher distinction. In the article under notice I advocated the claims of what I like to call the "cordon-trained bush," consisting as it does of so many main branches, or cordons, rising from the base of the tree. Even

from the start, such branches are sturdy and rigid, and become more so as they grow older. Some are more upright in growth than are others, according to the habit of the variety, but all are practically rigid and strong enough to carry a heavy crop of fruit without props or help of that sort. This rigidity and strength of branches are secured by shortening the terminal summer shoot at winter pruning to within 9 ins. of its base. The pruning is repeated each year in the same way and at the same time. Mr. Pearson speaks of "a cup-shaped bush which," he says, "is quite good for amateurs and admired by me, but that it has certain serious disadvantages, because," as he says, "to make a really nice-looking tree of it, it is necessary to bend out the branches at their base, and then turn them upwards and support them with stakes while young, and even

throughout their subsequent career." I must confess that I have no knowledge of a system of training bush trees in which the main branches are required to be kept in leading strings for so long! Then Mr. Pearson goes on to say that he prefers the pyramidal form of training for the Apple, rather than the bush. One of the greatest charms of the art of gardening lies in the fact that there is scope enough for each one to indulge in his own predilections as to methods and practices of culture, and yet for each to reach his own goal in his own way. For my part I much prefer the bush when trained in the way I have attempted to describe, rather than the pyramid. The latter is largely made up of its main stem, or centre column, and the base of the main branches arising from the same, and from which little or no fruit is ever gathered. The tapering shape of the tree reduces its fruit-bearing capacity very considerably, and its height exposes the fruit to damage from high winds. Moreover, it is more costly in management, entailing more labour in the use of steps and ladders in pruning and in gathering the fruit. Heavier crops of fruit are, in my opinion, to be obtained from the same area of land from bush trees, the method of training exposing the branches to a greater diffusion of light, air and sunshine than does any other method of training I know. Besides, the trees can be pruned and the fruit gathered from the floor level—no small advantage where many such bushes are grown. Their lower stature also protects them more or less from storms of wind.

However, it is on the subject of spur pruning which I advocated in my article that Mr. Pearson is so severe upon me. He says, "I have long ago come to the conclusion that of all the evils which fruit growers suffer from, close pruning is the most disastrous. Yet Mr. Thomas says the spur system consists in cutting back all side shoots growing out of the main branches to within (in the case of the stronger shoots) two buds of their base, and in the case of shoots of moderate vigour to within one bud of the base. Now," says Mr. Pearson, "this to my mind is rank heresy, and the result nothing but strong wood growth, and no fruit could by any possibility result until the tree was either exhausted or very far stricken in years." I hope by now that Mr. Pearson's indignation has somewhat cooled down, and that he will permit me to ask him a question or two. Has he ever seen the branches of a fully grown spur-pruned trained Pear tree growing against a wall in full flower in spring, and in autumn laden with their crops of fruit? Has he not seen old Apricot trees, grown and pruned on the same method, equally as happy and fruitful? Has he not also seen the spur-pruned branches of espalier and cordon Apple trees equally as happy and fruitful? Of course Mr. Pearson has. Would he be surprised to hear that such trees had been pruned on the spur system of pruning for generations by the best gardeners of other days, as well as by those of the present? Mr. Pearson is a bold man to condemn a system so venerable and so venerated as this for its great services in the past in dealing with fruit trees grafted on dwarfing stocks and grown in restricted positions such as I have had in my mind. What then, may be said of Mr. Pearson's contention that, if this old system of pruning is persisted in, it will lead to the disastrous results he predicts? and may I further ask what has Mr. Pearson to offer us in its stead? A system which I presume is his own—at any rate, I have not heard of it before—namely, a modification of the old system, which I think may justly be termed a sort of bastard spur pruning. It consists in cutting back the summer

shoots of the main branches at winter pruning to within six buds of their base, instead of two buds, as I advocate. By doing this he wishes growers to understand that after two young shoots have appeared at the top of the cut shoots the following summer, and they have been stopped or summer-pruned at the sixth or seventh leaf, the undeveloped wood buds below will be converted during the summer and autumn of the same year, or the year after, into fruit buds. Will they, though? They may—some of them—and they may not—in which case a bare part is left on the shoot ever afterwards. One of the weak points in this suggested method of pruning lies in the fact that the space is so large that the sap is unable to force all or any of the dormant wood buds into blossom buds as claimed for it: whereas when the shoots are cut back to within two buds of their base, as in spur pruning, the force of sap is so concentrated that the latent fruit buds at the extreme base of the cut shoot are compelled to develop themselves. Readers

in doubt can find confirmation of this if they will take the trouble to examine the groups of spurs which follow such pruning. They will find many of them there—flower buds comfortably nestling at the base of the cut shoots. Is it quite fair for the Editor to butt in, in a case of this sort, in order to support the critic's case against the criticised before the latter has had an opportunity of replying?—OWEN THOMAS.

[The Editor reiterates that he thinks in practice Mr. Pearson and Mr. Thomas have much the same system of pruning in mind. Mr. Thomas speaks of the "latent fruit buds at the extreme base of the shoots," which it would seem he has not taken into consideration when pruning to two eyes. If, as appears probable, Mr. Thomas means to prune to two *strong* eyes, Mr. Pearson would, no doubt, almost agree with him. If, on the other hand, Mr. Thomas really means to cut to two eyes, most up-to-date fruit growers would consider it an outdated orthodoxy rather than "rank heresy," as Mr. Pearson phrased it.]

THE PYRENEAN SAXIFRAGES

The following notes on the Pyrenean Saxifrages "At Home" should be very helpful to the Alpine grower.

THE Pyrenees are the richest centre in the world for Saxifrages. They are a real "centre of creation" for the family. *Saxifraga longifolia*, which has been grown in our gardens for more than 150 years, is the best known of all. It covers limestone rocks with a south aspect throughout the chain and reaches to the Sierras of Sagra and of Aitana in Spain; but there it is a form approaching *catalaunica* (Boiss), which is rather *S. lingulata* (Bell).

The typical *longifolia* is very popular as a garden plant because of its ease of culture, but it is certainly inferior to *lingulata* of the Maritime Alps. I never saw anything more wonderful than *lingulata* on the precipitous cliffs on the north side of the Alps above Nice. They bear long spikes of flower, some of them 2½ ft. long overhanging the path. The flowers of *lingulata* are pure white with a red stalk, and the leaves narrower and longer than those of *longifolia*. The culture of *lingulata*, although easy, is not so simple as that of *longifolia*, which is, unfortunately, monocarpian. It dies after flowering, which is not the case with its alpine sister. On the Spanish side of the Pyrenees *longifolia* seems to be stronger growing than on the north side. Last year, however, I went there to find seeds of *longifolia*, which at Floraire never can be got pure because of its being cross-pollinated by insects. We found that on both sides of the chain none had flowered or, at least, none gave seeds. It was explained to me that this is often the case and that some years they fail to get fertilised. This year they gave quantities of seed, so that I was very successful.

The group *Euaizoonia* is but poorly represented in the Pyrenees, but the *Dactyloides* species are so numerous that they seem to be the *fond de la végétation* of the whole chain. The most extraordinary of them is the rare *cuneata* (Willd) growing in the cliffs in the neighbourhood of Pamplona on the Spanish side. Boissier introduced it in his wall at Valleyres in 1838, and the plants are still there, having grown undisturbed since that time. They are now very large tufts, very beautiful to see. I saw them in my days of adolescence, and the sight of those splendid

Saxifrages certainly incited me to grow alpiners and to become a gardener.

The type *moschata* (*muscoïdes* of some authors) is such a variable one that the name varies in

together and to study their characters. Of course, some of them (*S. S. aquatica*, *ajugæfolia*, *capitata*, *tenella*, *sedoides*) are fairly fixed types and vary little. All those, however, belonging to *cæspitosa*, *muscoïdes*, *aphylla*, *gemmaifera* and *exarata* are so numerous that it seems impossible to study them well except in cultivation. For that reason I have begun the culture of them all. If any of your readers wish to help me in this direction I should be glad to get into correspondence with them.

S. aquatica sometimes forms in the Pyrenees fields of green foliage covering acres and acres of ground where nothing else can be seen. In ascending the Pic du Midi-de-Bigorre (there are several Pies du Midi) we found a station of it covering quite a *land* (perhaps two and a half acres) of ground. The plant is thick and tall (sometimes 3ft. with the stalks), bearing large pure white flowers. *S. ajugæfolia* is everywhere and covers the interstices of the screes at low and high altitudes. I found it and *Dioscorea pyrenaica* growing together.

On the surface of some rocks we found the rare *S. Clusii*, very curious with its reddish shining pilose leaves, growing at the foot of the cliffs, where we came across, but could not get, *Lilium pyrenaicum*.

We found the very rare *Bartsia spicata* in the Val de L'Hérins above Aste, the village where Tournefort had his seat when he visited the Pyrenees to study its flora. This valley seems to be particularly rich in rare things.

Floraire, Chêne Bourg, Geneva. H. CORREVON.

[All lovers of the mossy Saxifrages will wish M. Correvon success in his attempt to

AMONG THE MOST BEAUTIFUL OF ENCRUSTED SAXIFRAGES—*S. LINGULATA*.

given to it by some botanists. M. Luizet made an extraordinarily interesting study of all these Saxifrages of the *Dactyloides* group, published in the Bulletin of the Société Botanique de France, from 1910 onwards. His work seems to me to be the best on this section. I searched for the types he mentions and found some of them, but not all, as it is slow, hard work. Next year I hope to be more successful and to be able to introduce them to the gardening world. We made a little alpine garden in the Jura in order to grow them all

classify the Pyrenean species. We shall hope some day to publish in THE GARDEN the results of his labours—ED.]

FORTHCOMING EVENTS.

January 17.—Royal Horticultural Society's Meeting.

January 19.—Meeting of the Linnean Society of London at 5 p.m.

CORRESPONDENCE

DUTCH BULB GROWERS INVADE ENGLAND.

CONSIDERABLE interest has been aroused in the bulb-growing district of Lincolnshire by the announcement that the famous Dutch firm of bulb growers, Messrs. de Graaff Brothers, Limited, of Noordwijk, Holland, have purchased some sixty acres of bulb land just outside Spalding. The bulb-growing industry has steadily grown until it is now one of the most important in South Lincolnshire. English bulbs are in every way equal, if not superior, to those grown in Holland, and an increasing acreage is yearly devoted to this crop. The rich, silt soil of Lincolnshire is practically identical with that in the bulb areas of Holland. It is understood that Messrs. de Graaff will adopt the latest Dutch methods of culture on their English bulb farm. Within a week of their purchase of the land huge steam ploughs were at work tearing it up. As the present season is now too far advanced for bulb planting, the land will be cropped first with Potatoes (for which Lincolnshire is famed), bulbs being planted as these are lifted. This is the first occasion on which one of the great Dutch bulb firms has entered into direct competition on the spot with English growers by starting a farm in the very heart of the English bulb district. It is not unlikely that, now the ice is broken, other Dutch firms will follow suit. All varieties of bulbs do well in the Holland Division of Lincolnshire, but Tulips and Narcissi of all sorts are the principal kinds grown.—W. A. JEFFS.

DUTCH V. ENGLISH-GROWN BULBS.

NOTICE "Somers," page 639 of THE GARDEN, expresses his appreciation of the Dutch bulbs ordered direct from Holland. His experience is quite contrary to mine. I ordered from a well known Dutch firm the following bulbs: 50 second size Hyacinths, five varieties, 7s. 6d.; 25 early Tulips 3s.; 120 Darwin Tulips in ten sorts, 12s. 6d.; 50 Darwins, mixed, 5s.; 100 Spanish Iris in ten named varieties, 5s.; 50 *Crocus purpurea grandiflora*, 3s.; 50 *Crocus Maximilian*, 3s., totalling £1 19s. I received good Hyacinths worth 12s. 6d., but the remainder were a very poor, rough lot. The Darwin Tulips to name were all second and third size. Two varieties were Cottage Tulips, one double early, the total value 7s. 6d. The 50 mixed Darwins were 15 first, 15 second, 20 third size, value 2s. 3d.; 25 early-flowering Tulips, 15 second, 10 third size, value 1s. 4d.; 100 Spanish Iris, all planting size, not a flowering bulb among them, value 1s. 3d.; 50 *Crocus Maximilian*, second size; 50 *purpurea grandiflora*, second size, value 3s. It will thus be seen that I received bulbs value 27s. 10d. for 39s. remitted. Many of the bulbs are too small to flower, and are thus of no value to an amateur, although I have allowed something for them in my prices. The values I have allowed are made in comparison with those of a well known firm of English bulb growers, taken from their 1921 catalogue.—J. W., *Brigstock, Wisbech*.

FRUITING OF THE FEJOA

THE enclosed fruits may be of interest. I have had over three dozen fruits on my plant of *Fejoa Sellowiana* this year. The three sent are of varying size. What is the normal size of the fruit in its native country? I also enclose two sprigs of *Rhaphiolepis indica rubra* in full flower. This shrub should, of course, flower in April or May, but it is in flower now and full of buds,

which up to the present have not been injured by the frost.—H. G. HAWKER, *Ivy Bridge, South Devon*.

[The fruits of *Fejoa Sellowiana* are edible; they are used in the same way as the Medlar and Quince for making jam and jelly.—ED.]

NEW YEAR FLOWERS.

IN THE GARDEN for December 31 I notice that you mention Christmas Roses and *Erica darleyensis* as the only flowers that "usher in the year." I should like to tell you of some of the plants and shrubs that were flowering in abundance in my little garden here on New Year's Eve. (1) Large bunches of *Chimonanthus fragrans* on an old tree 12ft. high—the beautiful deep yellow flowers not the grey ones. (2) *Camellias*. I picked a large basketful of these, semi-double. I cannot discover the name; some of the flowers look like *Donkelaari*, but others are streaked with white. It is an old tree against a wall and has hundreds of blossoms every year. (3) *Daphne odora*, grown under a verandah, covered with large blossoms and glossy green leaves. (4) *Lonicera Standishii*, flowering splendidly. (5) *Cyclamen persicum*, flowering well, and also the *C. hederifolium*. (6) Violets in abundance; the large-flowered, long-stalked single ones. (7) *Coronilla glauca*. (8) *Jasminum nudiflorum*. (9) The pink Lenten Roses. (10) But the pride of my garden just now is an *Acacia Baileyana*, about 20ft. high or more, planted in 1917 and moved several times. It is now a mass of feathery yellow sprays, as beautiful as any on the Italian Riviera. None of these plants are protected, except the *Daphnes* now and then during a long frost. I send this little list hoping it may interest some of your readers and perhaps encourage them to grow these winter-flowering plants and shrubs.—CAVENDISH BENTINCK, *Dawlish, S. Devon*.

[*Jasminum nudiflorum* is of course, a regular and welcome winter-flowering plant, but the hybrid Lenten Roses seldom flower so early, at any rate, around London. The *Daphne*, *Lonicera Standishii*, *Camellias* and *Mimosa* make those of us—and we are the vast majority—who have to garden in a bleaker climate envious. The Great Western Railway Company have, after all some justification for comparing South Devon and Cornwall to the Riviera.—ED.]

EARLY FLOWERING OF IRIS UNGUICULARIS.

I HAVE read with great interest this correspondence, and from a small clump in my garden since October 1, 220 flowers have been picked. The clump, which has been left undisturbed for the last eight years, is in very poor sunbaked soil. The only attention ever given to it is in the summer, when any long foliage is pulled out or broken off and all dead grass—for tidiness sake—taken away. *Daphne indica* on a west wall is flowering earlier and better than I have ever seen it.—R. A. MEARES, *Falmouth*.

LATE-FLOWERING ROSES.

RIGHT up to the end of the year Roses have been flowering with wonderful prodigality in South-Western Scotland. In several gardens in this peninsular parish, which has the sea on all sides save one, *Wichuraiana* varieties, such as the floriferous *Dorothy Perkins* and her beautiful white derivatives, are blooming almost as freely (though with somewhat less artistic effectiveness) as they did during the months of August and

September. As late as the second week in December I had marvellously large and effective flowers on such fine varieties as *Corallina*, *Fran Karl Druschki*, *Lady Pirrie*, *Crimson Emblem* and *Bouquet d'Or*, the fairest daughter of the venerable *Gloire de Dijon*. *Campions* and *Primroses* have been blooming quite freely wherever they found protection from the desolating winds.—DAVID R. WILLIAMSON.

HORNBEAM AS A HEDGE PLANT.

IN the interesting article on garden hedges in your issue of the 10th ult., the writer says that it is scarcely surprising that the demand for the Hornbeam for hedges has of late years greatly revived, as its value for old time effect has become more fully recognised. I regret to say that I put in some hundreds of yards of Hornbeam hedge a dozen or so years ago and I would advise no one to repeat the mistake. The Hornbeam appears to me to have no advantages over the Beech and to be in every way inferior. It is never so effective as the Beech, whether in the early spring, when the leaves are breaking, in summer or in autumn. It is like a poor edition of the Beech in form of leaf and in richness of colour; and in the North, at all events, it drops its leaves as early as December, while the Beech continues to bear the far richer coloured leaves practically until the time for its beautiful young green leaves to appear.—J. H.

AN APPEAL FOR THE LITTLE GARDENS OF RHEIMS.

ALTHOUGH the war is really over, the effects of the catastrophe are still appallingly in evidence in the devastated districts of France. All the world has heard of Rheims, and few people were left unmoved by the terrible destruction of its glorious cathedral. Constant bombardment for four years worked terrible havoc among all the buildings of Rheims. Now, little by little, these are being reconstructed, but this generation will not see a complete restoration of the ruined city. The poorer quarters of the city were entirely destroyed, and during the greater part of the war the old people, women and children were sent away to the safe South. That is, those went who did not elect to stay on and face the dangers. These latter sent their children to schools which were carried on in the champagne cellars, and most of them lived in underground shelters. One of the chief citizens who "carried on" in Rheims during the war years told me that he became so used to going about on all fours, to avoid shot and shell, that he ended by forgetting that this was not the normal way for a man to walk. Most of the people had their houses and all their belongings destroyed. This has fallen heavily on the poor, the loss of their little all being irretrievable until Germany is made to pay up. When it was no longer necessary to live in shelters and cellars the people who had remained in Rheims found themselves homeless, and the returned exiles were in like condition. Now, all among the ruins one sees huts made of old planks, pieces of rusty corrugated iron, wooden cases, cube sugar-boxes, sacking, etc., where whole families live, and where, during the bitterly cold weather, many die from exposure. These poor people find work in the fields and vineyards round Rheims, and among the reviving industries of biscuit-making, velvet manufacture, in the reconstruction works and in the champagne cellars. The Municipality of Rheims has gradually put up four villages of huts (north, south, east and west of the city) to house the returning poor. These huts are made of wooden planks roughly put together, through which the cold penetrates in winter and the heat scorches in summer. Two

of the villages are on the sites of old battle-fields and shell-holes ruined houses, masses of barbed wire and war *débris* of all kinds still abound. There is no money to construct roads or to tidy the place up, and under present conditions the inhabitants add to the squalor by throwing all their rubbish out of the doors and windows. The most spacious lodgings have four rooms, and there are generally three lodgings to each hut. Old couples and single people have only one room in which they sleep, cook and often work at basket-making, chair-mending, etc. The greater part of the married people have large families; very few have less than six children. Just opposite the hut where I live with the British District Nurses (working for the Americans) is a family of ten boys and one girl. The youngest is three months old. Five children of this family are dead. This is by no means unique.

All French people are born gardeners, and they live chiefly on vegetables. I have started a little *œuvre* among these villages of huts. The authorities have given permission to the people to cultivate all available space round their dwellings, with the result that this year I hope these dirty, sordid, miserable places will be transmogrified into Garden Cities. The people have taken up the idea very keenly. My aim is to help the people themselves to better their conditions. The gardens will be beneficial in many ways—the vegetables will be an economy, the flowers will bring beauty and consolation, the cultivation of their plot will interest the owners and keep the men at home in their non-working hours, and also be a joy and distraction for the women who have nothing to lighten the grey monotony of their lives. Also the gardens will tidy up the whole village and give an air of prosperity and trimness which are now lacking. Then, too, the ownership of these little fenced-in gardens gives a pleasant sense of proprietorship which everyone enjoys having. The people can be private and have their meals and read in the open in the summer. These *jardnets* will remove the mud and *débris* from their doors. In August prizes will be given for the best gardens, and special prizes for those which have been cultivated by the boys of the family. The Municipality of Rheims has given me about two acres of ground which surrounds the Foyer Féminin (a club for girls and women started by the Americans, but now carried on by the French). This ground has been made into a flower garden and recreation ground for the Foyer Féminin and a vegetable garden which supplies the club with vegetables and grows plants for sale and for giving to the little gardens of the barrack villages. A new plant is a real joy to these poor people, and I am encouraging the true gardener's spirit of exchange among them. One poor widow woman, who lost all three of her sons in the war, finds her only joy and consolation among the flowers of her tiny garden. Her face lights up all over it. I give her a cutting or plant. Another widow, who has an only child, a boy of fourteen, has made quite a wonderful little garden out of the tiny space she was allowed last year. She never bought vegetables all through the summer, and also contrived to have a little border gay with flowers. She has made an arch over her tiny gate, and I am giving her a climbing Rose to cover it. My little *œuvre* is to help and encourage the people, and I want to be able to give seeds and plants to every garden. My great ambition is to have a climbing plant on every lodging (Roses for choice) to hide its intense ugliness. So I am sending out this appeal to ask everyone whom it reaches to send me the ends of their seed packets when they have sown their own gardens, or to give me a few full packets or the

money with which to buy seeds or plants. The Royal Horticultural Society has given me a most generous gift of vegetable seeds, enough to sow all the little gardens and the Mother Garden at the Foyer Féminin. So now all that I need are the flowers which by their beauty will do much to raise these stricken people out of their sordid misery. They will bring hope to the hopeless, consolation to the bereaved, and joy and loveliness to all.

"Hedge thy dwelling round
With the Divine companionship of Flowers."

Gifts should be addressed to Miss Slade, Foyer Féminin, 26, Rue Simon, Rheims, Marne, France.
—VICTORIA SLADE.

THE MISTLETOE AND ITS HOSTS.

IN the interesting note on *Viscum album* in THE GARDEN of December 24 the writer states that he has seen it on both the Wych and English Elm, and also that it is said to have been found on the Cedar of Lebanon and Larch. In some Pine forests abroad Mistletoe is regarded as a pest, so it is, perhaps, not surprising that it should

Gardens at Oxford. In no other place in the world can Mistletoe be seen growing on such a variety of trees, all within one acre of ground. The seeds appear to have been naturally carried from the Lime trees near the road to the Weeping Willows at the back and to have spread from them to the following: *Pyrus Malus*, *P. aria*, *Cotoneaster Lindleyi*, *Juglans niger*, *Robinia Pseudacacia*, *Crataegus orientalis*, *C. tanacetifolia*, *Æsculus octandra*, *Ostrya carpinifolia* and *Acer monspesulanum*. The Mistletoe appears to be affected by some of its hosts. On the *Ostrya* some fifty plants all exhibited the characteristic golden tinge of green, but the bushes growing on the *Æsculus* and *Crataegus tanacetifolia* were a dark holly-green and bore smaller leaves, and, indeed, appeared to be a different variety, though grown from the same seed as the rest.—H. H. W.

THE ROOTS OF THE STATELY EREMURUS.

THERE are few things in the plant kingdom so weird and curious as the roots of the *Eremurus*. The single crown is like a giant

THE CURIOUS ROOTS OF THE EREMURUS.

have been recorded on such trees as the writer names in this country, though it will not flourish on them. I have never met with it growing on any species of Elm, even where it grows plentifully on Lime trees close to them. On many a journey, particularly in the South-West of England, one can see, without leaving the train, that the Apple tree is the favourite host plant, but in Herts and Essex it grows far more plentifully and easily on the Elm. I have seen it growing to perfection on the Aspen Poplar and also on the Hawthorn. In an Essex cottage garden I once saw it growing well on an old Gooseberry bush. So rarely is Mistletoe to be met with on the Oak that I began to regard its presence there and its Druidic associations as a myth, till the Vicar of Hambleton (who kindly measured with me for THE GARDEN the ancient Yew tree over soft, in girth) revealed one of its rare, oak-hiding places, where I trust it may remain for as many centuries as the famous Yew. My chief object in writing is to record the names of the numerous host trees in the Botanic

starfish. Thick, fleshy, tapering roots are seen radiating from a common centre. With old well established clumps there are occasionally as many as nine or ten crowns to a root, and as each crown is capable of throwing an inflorescence, the promise of bloom is truly wonderful. Much of the interest in these plants, as in many others, lies hidden underground. Verily plant life is full of strange things, and if plants can reason, no doubt they think the same of us. There is a reason for the strange appearance of these roots, as, indeed, there is a reason for everything a plant does if only we think it out. It would naturally be expected that roots should differ in structure according to the various tasks assigned to them. In the case of *Eremurus* the plant sends up robust flower-spikes, as tall as or taller than a man. When we consider the strength of the inflorescence and the length of the spike of this Lilaceous plant, we can realise the great root pressure and amount of nutriment necessary to support the plant. These fleshy roots are specially developed as

structures for reserve material and the absorption of nourishment, while at the same time by their wide expansion they provide the necessary anchorage in the soil. As one might assume from the

shallow roots, the *Eremurus* delights in a moist soil and prefers an abundance of water in the growing and flowering season.—HERBERT COWLEY, *Lunbridge Wells.*

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Seakale.—This is more easily forced now than the earlier batches were. Should a constant supply be required it will be necessary to place some roots into their forcing quarters about every three weeks. It is never advisable to use too much heat in forcing Seakale. The best results are obtained when the crop is forced gently. Preparations should be made now for forcing some of the roots where growing. Place pots or boxes with movable lids over a portion of the bed and cover well over with leaves and strawy manure. Some of the finest Seakale is produced when forced in this manner.

Carrots.—Should a sowing not yet have been made as advised in the calendar for December 17, the present is a good time to make one. Select an early shorthorn variety and use a fine light soil. The seed may be sown in rows or broadcast, but the former affords the better chance of having the soil hoed occasionally to aerate it.

Potatoes in Pots.—For an early supply of new Potatoes to precede those in frames, pots or boxes afford suitable means for growing them. The former should be from oins, to roins in diameter, and boxes should be about that in depth, and dimensions otherwise of convenient size for handling. Let the compost have a liberal amount of well decayed flaky leaf soil in it and see that good drainage is given. The seed selected for this sowing should be nicely sprouted and be of an early variety recommended for this work. Space should be left when filling pots or boxes to give a good top-dressing later on, and plants should be grown in a light airy position when through the soil.

The Hardy Fruit Garden.

Raspberries left untied in the autumn should be attended to now, making sure at the same time that the supports are all good. Where the canes are centred round a stake, loop them all up proportionately and not in a too besom-like manner. The training on wires or similar arrangement calls for even distribution to best advantage. Where a new plantation has been made the method of support should be decided upon and placed in readiness when time permits, so that there shall be no delay when young growths require tying up later. Should these latter plants not have been cut yet, do so now to within about oins. of the ground, and give them, as well as the established plants, a mulching of decayed leaves and manure.

Pruning.—During favourable weather push ahead as rapidly as possible with this work. In dealing with trees on old walls, which may have become defaced and which offer such a hiding place for insect life, it will be of great advantage, where it can be done, for the trees growing against the most offending portions to be entirely liberated, and the wall cleansed with a rough brush and afterwards treated with some insecticide.

The Flower Garden.

Perennial Climbers.—In addition to *Vitis* and Pillar Roses, recently touched upon, there are several other valuable climbers which should among the best we have the *Bignonia*, *Clematis*, receive consideration where such plants are required. *Eccremocarpus*, *Humulus*, *Jasminum*, *Lonicera*, *Polygonum*, *Solanum*, *Tropæolum* and *Wistaria*. While all are hardy, consideration should be given when selecting the positions for the plants, that those known to possess the most robust nature be given the coldest aspect. In view of the permanent character of such climbers the ground should be well prepared for them so that a good start is assured. The different uses to which such plants may be put are several, among which may be mentioned the clothing of pergolas, tripods, dead trees or stumps, and for screen work. Some, more particularly *Clematis*, *Lonicera* and *Tropæolum*, are splendidly adapted for association with other plants. To give one or two examples, *Clematis* entwined among Roses, early flowering *Lonicera* with *Vitis* and *Tropæolum* in conjunction with any plant which gives a spring display and is somewhat bare later in the season, such as the

Almond tree. The *Wistaria* should be so planted that its graceful pendulous flower heads may be shown off to advantage and allowance made where supports are to be erected that they are sufficiently strong to carry the growths as the plant eventually develops into a large-stemmed one.

Plants Under Glass.

Amaryllis.—Some of the strongest and earliest ripened bulbs are throwing up their flower spikes and should be removed to a warm house. The drainage of the plants will have been put in order, and after removing the top crust of old soil, give them a rich top dressing. The bulbs will get sufficient moisture for a little while by occasionally spraying them, but when the growth is more active dryness must be guarded against.

Cyclamen.—Young plants growing in pans or boxes should be potted into 6½ sized pots, using a light compost and not potting too freely. For some time yet the young plants should be kept growing in a warm moist temperature and occasionally fumigated should thrips show.

Mignonette.—This old favourite is always appreciated in the dwelling and flowering house. Autumn sown plants requiring a further pot-on should receive it, using a good loamy sod with some old mortar rubble added. This plant requires firm potting, and should be grown where plenty of light and air reach it. H. TURNER.
(Gardener to the Duke of Northumberland)
Albany Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Hot-Beds.—Take advantage of frosty weather to have a good-sized hot-bed made up, as this will be found of inestimable value to the gardener who is expected to produce forced vegetables during the early spring months. Construct the bed in a sheltered spot facing south, so that full benefit may also be derived from the heat of the sun. The materials should consist of freshly fallen leaves and stable manure. Mix together and leave in bulk for a few days before finally forming to the desired size. Firm treading of the materials is essential as the making of the bed proceeds, and to ensure the heat of the bed lasting for a reasonable period it should be built to a depth of 5ft. The bed may be left to heat up before the frames are placed in position, but, as there is plenty of moisture in the leaves at present, fermentation will speedily take place. A suitable compost should be prepared beforehand and used for sowing or planting in as necessity demands.

Sprouting Early Potatoes.—For early forcing these should be sprouted in shallow boxes. Avoid coddling in any way and aim at producing sturdy growth. The Ashleaf varieties are all suitable for forcing. Sharpe's Victor, May Queen and Duke of York are also good varieties for this purpose.

Lettuces and Radishes.—Sow a pinch of early Lettuce seed in a box so that the subsequent seedlings may be pricked into hot-beds later on. Turnip-rooted Radishes may also be sown thinly among the early Carrots in frames, as these will be ready to pull before the young Carrots require the extra space.

Plants Under Glass.

Chrysanthemum Cuttings.—The bulk of the bush varieties will now have produced "cuttings" freely, so no time should be lost in having the necessary quantity inserted. Boxes are most convenient where large quantities have to be struck. Use a fine mixture of loam and leaf-mould, with a liberal quantity of sharp sand. Choose firm, stocky growths that are breaking away from the base of the stool.

Forcing Plants.—Further batches of Azaleas, Rhododendrons and shrubby *Spiræas* should be placed in heat for succession. Most of these plants will be found to force more readily now.

Begonia Gloire de Lorraine.—Batches of these which have been at their best during the Christmas period should now be cut over and placed in genial

warmth so that they may be encouraged to produce strong "cuttings" for early work. Keep the plants on the dry side for a time, giving the stools a spray overhead occasionally.

Cytisus fragrans.—Large specimens of this sweetly perfumed plant are often grown in comparatively small-sized pots, so should now be assisted with frequent waterings of liquid manure. Being a cool greenhouse plant, this *Cytisus* resents any attempt at early forcing, as when subjected to much heat at this time it rarely flowers well.

Calceolaria Clibranii should now be taken in hand and repotted. To obtain large specimen plants those that flowered during the late season in 6in. or 7in. pots should now be placed in pots of from 10ins. to 12ins. They revel in a mixture of good fibrous loam and leaf-mould with a sprinkling of old lime rubble added.

Hydrangea Hortensis.—Where these are required in flower early in the season a few plants showing well developed buds may be placed in a warm pit. When the plants are freely growing occasional doses of weak soot-water may be given them, varied at times with liquid manure.

The Flower Garden.

Preparing Flower-Beds.—Where beds or borders are not occupied with spring-flowering plants opportunity should be taken to have them suitably manured and dug over. Use thoroughly decayed manure for this purpose, as many bedding plants produce over-luxuriant foliage with corresponding scarcity of flower when too generously treated. Edge the beds neatly as the work proceeds. JAMES McGRAN.

(Gardener to Sir Henry H. Bouldsworth, Bart.)
Loatham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Greenhouse Cleaning.—Cleanliness is one of the chief essentials in successful gardening, and is of prime importance in indoor operations. If not already done, no time should be lost in cleaning the interior of plant houses generally, for very soon there will be little time to spare for such work. The roof glass should be washed down as well as all wall surfaces, which should afterwards be sprayed with carbolic acid, using 4oz to every 3 gallons of water. All wall surfaces should then be lime-washed, adding half a pound of flowers of sulphur to every 3 gallons of limewash. The best fixing medium for limewash is skim-milk; linseed oil is also used. Size is often made use of, but it is no good for the purpose, as the lime soon destroys it. All propagating cases and frames should be treated in the same way, replacing the old plunging material, if necessary, with fresh. Stages and benches should also receive attention, renewing any standing material which is old and sour. This is very important, as plants never do well when standing on a dirty and sour medium. Where pea gravel is used on benches, it should be washed; other material, such as sifted ashes or coke breeze, should be discarded and replaced with fresh. The benches when cleaned should be watered with the carbolic acid solution as advised for the walls. There are, of course, plenty of good proprietary washes if one prefers to use them. A disinfectant of some sort is essential, especially where collections are affected by that all too common pest, cyclworm. All the foregoing labour may to many seem unnecessary, but it is only by strict attention to such details that success is assured in plant growing.

Seed Lists.—The opening weeks of the New Year usually bring a shoal of seed catalogues. Orders should be placed early, especially for such kinds as should be sown in January or February. Always order from a reliable firm, even if their seeds cost a little more. It usually proves economical in the end. It has to be taken into account that the work of growing is just the same, so that it is well to have every possible guarantee that the strains of seed purchased are of the best. From the great variety offered it is rather difficult for the inexperienced to make a suitable choice. It is, in any case, best to trust to known varieties if they are wanted for a definite time or purpose, making it a rule, however, every year to try something new in addition.

Potting Soils.—It is important at this time that loam, leaf-soil, peat and sand should be placed under cover, so that they may be in suitable condition for potting and seed sowing.

Lime.—The use of lime is too often neglected in potting soils, although its value is generally recognised in outdoor gardening. Its use is of prime importance in potting soils, which is usually obtained from old pasture or park lands, which

too often have been neglected as regards regular liming.

Plants for Forcing.—Continue to introduce plants into a heated house for forcing. Care is, however, necessary, for many plants are spoiled each year by too sudden a change of temperature. Shrubby plants from outdoors or bulbs from cold frames should be gradually accustomed to a high temperature. In the case of bulbs it is also very important that they be well rooted. This implies that they were potted in good time last autumn. Lilies of the Valley respond quickly to a temperature of 80° to 85°, especially if they have been stood in the open for some weeks with the crowns well exposed to the weather. Needless to say, plants grown in so high a temperature have not got the lasting qualities of plants grown in cooler quarters.

Chrysanthemums.—Where exhibition blooms are grown a start is usually made with propagation during December. Where grown purely for decorative purposes, cuttings may be inserted from now onwards until the end of March, or even during April. Propagation in March and April is to produce plants for growing in small pots to furnish the stages in the conservatory. They are also excellent for use in the dwelling-house, and in this form are worthy of more general cultivation. Later on I hope to enter more fully into the details of their cultivation. In taking cuttings, firm, medium-sized shoots some 3 ins. in length are best; cuttings from the stem should, where possible, be avoided. Sometimes there is very little choice, as many fine new varieties are

notoriously bad stock-makers, a good example being that beautiful single variety, Caterham Bronze. With such varieties one must take what one can get. Better plants of some varieties are obtained by fresh cuttings taken later on from the young rooted plants. In rooting cuttings for exhibition work it is usual to insert the cuttings singly in thumb pots. For ordinary cultivation this is not necessary; they may be dibbled fairly closely into pots or into boxes where a quantity of one sort is required. They root readily in a shallow cold frame or under hand-lights stood on a bench in a cold house. So treated they will take a little longer to root, but the resulting plants are generally stronger and sturdier than those subjected to heat. Care should be taken that they are not kept too damp.

Carnations.—Continue to keep the Malmaison varieties on the dry side. Do not on any account get the foliage wet; allow just enough water at the root during winter to keep them from shrivelling, and no moisture on the foliage. This is the only sure preventive and cure for rust. Spraying with supposed preventives is worse than useless; it just provides the needed moisture for the disease to start and propagate itself. Rooted cuttings of Perpetual Flowering varieties should be potted off as they require it. Continue to insert cuttings as they become available. Remember that lime in some form in the potting compost is essential for the well-being of all Carnations.

J. COULTS.

Royal Botanic Gardens, Kew.

THE FIRST KNOWN DAHLIAS

The writer endeavours to clear up the mystery surrounding the introduction of the Dahlia to Britain.

AMONG the interesting discoveries that I have made during some recent enquiries into the history of the Dahlia, there is one, in particular, which deserves the attention of those readers of THE GARDEN who are concerned with that subject. There has been so much taken for granted and apparently so little of the historical matter submitted to the test of critical examination by the majority of writers on this flower that the few notes which follow may be helpful to anyone who may henceforth desire to pursue a course of independent investigation.

Every student of floricultural history knows that it is generally stated that the first introduction of the Dahlia into England was by the Marchioness of Bute in 1789. But nobody ever tells us what was the name or names of the varieties so introduced. In fact, some of the writers lead us to suppose that there was only one. My researches prove beyond question that the date given is an initial blunder and one that has been permitted to go unchallenged for a hundred years or so, and that the real date should be put at least nine years later. My reasons for this have already been published.

The Bute introductions were undoubtedly lost through want of knowledge as to the culture necessary or from some other cause. They were followed by the second introduction, which was due to Lady Holland in 1804. The discovery alluded to was made recently at the Natural History Museum, when I was there on other work connected with the Dahlia. Dr. Rendle very kindly suggested that as he had under his care some old dried specimens of Dahlias he would be pleased for me to send them in case they might be of any service. Upon my assenting, they were brought forth, and it is a most remarkable circumstance that nobody that has ever taken any interest in the historical aspects of the Dahlia should have seen these specimens, otherwise they would certainly have been mentioned. It may be, of course, that the existence of these interesting specimens

was unknown to former writers as it was to me—it may be that for the purpose of comparison and identification the various coloured figures in the botanical and horticultural publications available were deemed sufficient. But whatever the reason, it is certain that these old dried specimens of Dahlias throw a new light upon Dahlia history which has hitherto been unknown.

Out of the total number there are eight which deserve our special consideration, and three of these are of the utmost historic value in helping us to come to a definite conclusion as to the names of those flowers which the Marchioness of Bute first introduced into this country. The reader who has read my article on the Evolution of the Show Dahlia in the National Dahlia Society's Year Book for 1915 will remember that the Abbé Cavanilles of Madrid named the Dahlias he received from Mexico, *D. pinnata*, *D. rosea*, and *D. coccinea*, each of which he figured and described in his "Icones."

Now the first of these dried specimens is intensely interesting and instructive for two reasons—firstly, because of the inscription written in ink upon the shell on which the flower is mounted; secondly, because the specimen itself shows clearly, as Cavanilles' figure does, that it was a semi-double flower. André Thouin's figure of the same flower in the *Annales du Muséum* also demonstrates this peculiarity, which is a remarkable one, considering that under English and German cultivation the blooms came absolutely single and are figured as such by almost every other authority since.

This is *D. pinnata*, otherwise known as *purpurea*, the *Georgia variabilis purpurea* of Willdenow's "Hortus Berolinensis," tab. xciii. The following is the inscription: "*Dahlia pinnata*, Cav. ic., p. 56 and 80, sent under the name of *Dahlia cœruleo-rubens*, C. G. Ortega (Lady Bute)." This colour description is in Cavanilles' own wording as the reader will see in his Obs. in the text to tab. 266.

The next of these specimens is marked "C. G. Ortega (Lady Bute) *Dahlia rosea*, Cav. ic., p.

33-1,265." It is quite a single flower, not so large in its dried condition as Cavanilles' figure of that variety.

The third one is a much larger specimen than Cavanilles' figure of it. It bears the inscription: "C. G. Ortega (Lady Bute) *Dahlia coccinea*, Cav. p. 3."

They are all undated, but there seems to be no room for doubt that, irrespective of any question as to the date of introduction by Lady Bute, these dried specimens were the three original varieties that Cavanilles received from Mexico and not seminal varieties bearing other names.

By the time Lady Holland had secured seeds and had grown them at Holland House for a year or two the original three had increased in number, and the remaining specimens in the collection at the Natural History Museum afford ample proof of the inconstancy of *D. pinnata* in coming semi-double. We could otherwise have been quite convinced of this by reference to the coloured figures of it in the various publications of the period.

Taking the fourth specimen, we find it marked "Lord Holland's Garden, *Dahlia pinnata-purpurea* N. 1." This flower is a large, flat-petalled single. The next one is also marked "*Dahlia pinnata-purpurea* No. 2, Lord Holland's Garden," and is a flower of great size, a single with broad florets about 5 inches in diameter. The following note appears at the bottom of the sheet: "This plant came from seeds in 1805. The colour is stronger and dries much better. 8½ feet high to the first top flower."

We get another example in the specimen marked "*Dahlia purpurea* N. 3, Lord Holland's garden." The centre is gone and the flower is smaller than the preceding one, but it is still as single as a flower can be. The inscription informs us that "This plant bears flowers of a deeper colour than No. 2, being a medium between 1, 2, 3 and 4, which is bipinnata. The flowers are double (?), but only 8 leaves were perfect." It is interesting to notice that although these old specimens are brown with age there is in each case the original shade of colour still more or less faintly visible.

Now although the majority of these old single Dahlias had only eight broad radial florets, some at times had more. That can be ascertained not only by reference to the published coloured figures, but by the specimens themselves. One of them is a case in point. It is inscribed: "*Dahlia rosea* seemly not, but only a variety," and at the bottom: "Lord Holland's Garden." In this there are nine florets of the ray.

Of the remaining specimens there is one, also a single, with eight florets still faintly showing the original yellow colour, marked "Lord Holland's Garden, *Dahlia coccinea*," and rather the worse for age. When this was figured in the *Botanical Magazine*, tab. 762, it had nine. Cavanilles' figure also depicts the flower with nine.

The last to be noticed is inscribed: "*Dahlia crocata*, Lord Holland's Garden." Both *coccinea* and *crocata* are always shown as singles, but they were smaller forms than *pinnata* and *rosea*, and more variable in the number of their radial florets, *D. crocata* in McDonald's Dictionary being shown with nine, while in the "British Flower Garden," pl. 282, it will be seen to have ten.

Such are the essential points of interest that occur to the mind of anyone examining the specimens. It must be admitted that they throw a flood of light upon the subject which, up to now, has never been suspected. That they should have remained hidden away all these years and never yet have been brought to the notice of our Dahlia historians is one of those inexplicable mysteries with which the student of floricultural history is occasionally confronted. C. FARMAN PAYNE.

Garden Specialists, **SOUTHWELL, NOTTS.**

GREAT SPECIAL OFFER of HERBACEOUS PÆONIES

The following list comprise the finest varieties in cultivation. They are all free flowering sorts. Strong roots with 3 to 5 eyes. We offer this charming set **1 Plant each for 21/-**, or customers may select which varieties they desire.

Packing and Carriage Paid for Cash with Order.

Albo Plena—Pure white.

Albatre—Ivory white.

Boule de Neige—Pure white.

Couronne d'Or—White with carmine edge, golden anthers.

Duo de Caras.

Duke of Wellington—White, yellow inside petal.

Duchessa de Nemours—White, primrose centre.

Emelle Lemolna—Deep carmine.

Feativa Maxima—Very large white

Fauet—Rosy white.

Mona. C. Laveque—Beautiful rosy salmon.

Madame Calot—Pale carnation.

Wm. ARTINDALE & SON, Nether Green Nursery, SHEFFIELD.

PLANTING SEASON.

HOW TO PRUNE ROSES & FRUIT TREES

A most helpful booklet by OWEN THOMAS, V.M.H. Sent post free on receipt of 11d. "COUNTRY LIFE" Offices, 20, Tavistock Street, Covent Garden, W.C.2.

SWEET PEAS AND HOW TO EXCEL WITH THEM. By HORACE WRIGHT, 9d. net, by post 11d. Published at the Offices of "COUNTRY LIFE," LIMITED, 20 Tavistock Street, Covent Garden, W.C.2.

A CORRESPONDENT this week calls attention to the difficulty of applying Mendel's Law to, for example, the Carnation. It is probably not wide of the mark to say that there are few subjects about which the average gardener knows less than about Mendel's Law. There are even to-day men whose business depends very largely on the raising of new plants who do not hesitate to describe Mendelism as "all tosh." There is no use in mincing words. There is much that is out of date, much that is reactionary in the horticultural trade. This obviously does not apply to the established firms who are at the "top of the tree," nor to some of the younger and wonderfully progressive firms who are rapidly climbing to that exalted position. These, however, represent but a small part of the nursery and seed trades. There are far too many who are content to dismiss Mendelism as "tosh," scientific research as a waste of money, and packing as of no importance. The methods of their grandfathers are good enough for them. Many of them carry on a precarious existence. In almost any other profession they would long since have been out of business.

The Explanation would seem to be in the fact that horticulture is, generally speaking, a badly remunerated profession. There are to-day many skilled head-gardeners with a very wide range of knowledge indeed who are drawing a wage lower than many dustmen. A similar standard of remuneration obtains in commercial horticulture, and so small is, even then, the margin of profit that it is evident that higher wages must depend upon the introduction and utilisation of labour-saving and waste-eliminating devices. To introduce such devices and to utilise to their greatest extent all helpful knowledge as exemplified, for instance, by the Mendelian Law, it is necessary to have directing intelligences of no mean order dowered with foresight and gifted with resolution, or with what the "man in the street" calls "push and go." Here is, then, a vicious circle with low wages explaining incompetence and incompetence making inevitable low wages.

Truth is Great.—To come back to our "text," the Mendelian Law, from which insensibly we had drifted away, one of the commonest arguments brought against the application of Mendelian theory is that it is not true or that it is true only of certain genera of plants and animals. That it is not applicable to Carnations, for instance. The law has been practically applied to such varied genera as Pisum, Primula and Cucurbita. It would surely be worth while closely to study its application to genera in which the component factors would appear to be more numerous and intricate. It is quite probable, nay! as far as certainty can be attained, it is certain that Mendel's Law as now understood is not a final statement of the facts relating to interbreeding. Were that, however, to be held a valid reason for neglecting newly acquired knowledge, however inexact, however imperfect, there would be an end at once to human progress. The greatest English scientist who has ever lived is universally admitted to have been Sir Isaac Newton. His discoveries were epoch-making. They might well be described as great new truths, yet when all is said, they were but approximations to exact truths; perhaps it will ultimately turn out not even that! None the less, much useful work, both practical and theoretical, has been built upon them. The same

might be said of the Atomic Theory, for instance, which, though now admitted to be inaccurate, has yet been, and still is, the very foundation stone of modern chemistry. Darwin's Theory of Evolution has done excellent service and been of much practical use to the thinkers of the world, though in some respects it is now considered anything but an accurate presentation of facts. It is very doubtful if man will ever attain—if he is ever intended to attain—to abstract truth upon even the simplest matter. What can with reasonable confidence be set down is that, century by century, decade by decade, we reach a little nearer to that great ideal. *Magna est veritas et prevalebit* some day! In the meantime let us put forth our best endeavours with the tools we have, imperfect though they be!

Good Tools.—If the foregoing paragraphs read something like a sermon, let it be forgiven! The Editor does not often wander into metaphysics. The present is a season when it is well to overhaul one's garden tools and take steps to have "done up" or replaced those out of repair. Lawn-mowers should be repaired and adjusted, picks and edged tools be re-sharpened, and some of the latest labour-saving devices be added as the particular requirements of the garden dictate and the domestic exchequer permit. It is a never failing source of

wonderment that tools so absolutely unsuitable for the purpose for which they are intended should continue to be made—unsuitable oft-times not only on account of bad materials, but because of radically bad design. This note was really prompted by the fact that the Editor has recently tried a trowel called the "Perfect," which is supplied only by Messrs. Carling, Gill and Carling, Limited, of Guildford and Godalming. It lives up quite well to its name. In a world where naught is perfect this excellent tool reaches as near perfection as the most critical could wish. The blade is so shaped as not to retain the earth; it is adequately, but not over-ranked. The steel is the best and the "bright" finish excellent. Economy on tools is surely the falsest of all economies imaginable, but it is one often made!

IRIS UNGUIULARIS WHICH HAS FLOWERED AND IS FLOWERING WONDERFULLY WELL THIS SEASON.

DO HEATHS REQUIRE PEAT?

The writer says not. Some of the best species and varieties, with suggestions for their culture.

ARATHER sharp slope of shaley loam, apt to suffer in summer from drought, does not perhaps suggest ideal conditions for many Heaths, but we nevertheless put in a goodly number of varieties some years ago, and, rather than reaping any regrets, this plantation has proved to be among the most satisfactory undertakings yet attempted.

The good qualities of Heaths "need no bush," but there is one which in these days of expensive labour stands out above all others. I refer to the fact that once your Heaths are established they never need any attention at any season. Even on a rough, open woodland slope, such as ours, they eventually overcome other herbage, which means the saving of a deal of work and an avoidance of that use of the brushing-hook which, however necessary it may often be, is not always an improvement in a semi-wild garden.

The first of the winter Heaths to flower here is *Erica mediterranea hybrida*, one of the most useful and more closely appertaining to the typical *mediterranea* than to its other parent, *E. carnea*. This is practically an all-winter bloomer, but just when it is coming into its best the two others mentioned will be getting nicely coloured; that is it precedes *mediterranea* whilst just about the same time the moss-green, plumose foliage of *E. lusitanica* will be hung with its countless little bells of the peculiar ashen whiteness and texture of burnt

paper. Of *E. carnea* there are many forms, of which the white one is the least valuable. Among the rest, the most pleasing is, I think, one of a clear rosy carmine, pinker than the type (often listed as "rosea") and a very lovely thing, especially when grown on a level with the eye. The white variety of *E. mediterranea* is first-rate, a pure white and a generous bloomer, but the best of the group is undoubtedly *E. m. superba*. This, though later in flowering, is bigger, rosier and better in every way than the type, which is saying a good deal.

Before the last of the above are out of bloom those of the *E. Tetralix* and *cinerea* set are opening their flowers. The most delightful of the former are the creamy white, glaucous-hued *mollis*, and the delicately beautiful *alba*. Another good one is *E. Mackaii*, whose large round bells are of a charming low-toned pink, and not less attractive is *E. Watsoni*, a *cineraria* x *tetralix* hybrid which inherits some of the best qualities of both parents. There is a double form of *E. Mackaii* and *E. T. Lawsoniana*, with flowers of a wild rose hue, is very lovely. All the members of the *E. Tetralix* clan appear to need rather more moisture than most others, and it is evident, if lessons afforded by the wild type be of any guide, that peat is their chosen medium.

E. cinerea is one of the best drought resisters with us, and quite the most effective variety for wide planting is *rosea*. This, as its name implies, has less blue in it than the type, yet it is a rich and

decided colour and one that is very striking in the mass. It is one of the first of the summer bloomers to open and lasts a long while in flower. The white variety of *cinerea* is also worth a place, this, as often happens in albinos, having foliage of a deeper green; and another splendid, though much dwarfier form is that known as *E. cinerea coccinea*, whose flowers are a fine, bold crimson. This last makes an excellent foreground or edging plant, and we have it fringing the brink of an old retaining wall that forms a part of our Heath bank.

Erica ciliaris, in some respects the most beautiful of all the native Heathers, is quite content with this sharply drained loam. The very large flowers in both varieties, the rose-purple and the white, are rendered even the more attractive and distinct by reason of the delicate tint of emerald which permeates the foliage. Since this species has rather a trailing habit it needs careful placing so as to prevent its being overgrown by others. *E. Maweana*, said to be a form of the above, with flowers more nearly approaching crimson, is one of the best of the genus, and many who have failed with the type have succeeded with this one. These, like those of the preceding group, are all summer bloomers and flower well into autumn.

Out of the many forms of *E. (Calluna) vulgaris* we have "concentrated" on some half-a-dozen. These include *E. vulgaris fl. pl.*, which excels over the type no less effectually than Double Gorse

"STOLEN MOORLAND." AN EFFECTIVE HEATH GARDEN.

does over the common form. *E. v. Alporti*, with very deep green foliage, is the finest crimson and *Hammondi* the best of the tall whites, both strong growers. *E. alba Serlei* is another white variety, rather more dwarf, and *tenuis*, a dwarf crimson-

is one that makes an admirable ornamental hedge. As a matter of fact, *E. stricta* is one of the favourites here, not only because its cool, shell-pink flowers are so welcome during the later days of autumn, but because the

australis must be afforded a space where, in the climate allows. Though not tender, it is liable to be cut back by severe frost and should therefore be given a sheltered site in all but our milder counties. For a good many years it has done well here, growing to about 4ft. The very large, long-shaped flowers, of an exceedingly vivid rose, are borne in terminal clusters (usually four or eight blooms together), and these distinguish this Heath from any other. Yet another of the genus which stands by itself is the loose-habited *E. Stuarti*, with white blossoms tipped with carmine. This, again, could not be mistaken, once its flowers have been seen. It is said to be a natural hybrid discovered in Ireland.

All these Heaths and others are flourishing, as I have said, in a free loam on a south-westerly bank. They have never had any peat, but some of the more precious were given a little leaf mould when planting. One of the prime factors which made for success in putting the plants in has undoubtedly been deep planting. We make the holes almost laterally, or at right angles to the lie of the land, they are deep enough to allow the plants to be sunk well up to the foliage (usually deeper than they were), the soil is firmed in with the handle of the spade and that is all. For most kinds we find spring the best season for planting, but the winter-flowering sorts are put in as soon as the autumn rains have soaked the ground. Should any of the Heaths

appear likely to suffer from drought during their first summer they are covered with light hedge-brushings, bracken or other green herbage, but they seldom need this and we rarely lose a plant.

N. Wales.

A. T. JOHNSON.

ERICA CARNEA AND ITS VARIETIES TOLERATE LIME IN THE SOIL, THEREIN DIFFERING FROM OTHER SPECIES.

scarlet. With these and, for the sake of their foliage—golden and bronze respectively—*E. v. aurea* and *cuprea*, one whose space is limited may close the vulgar list, unless he is tempted to add "just one more," viz., the dainty and refined *gracilis* in white. But it is a list so rich in good things that if I were doomed to confine my attention to one group of Heaths I should unhesitatingly select these garden forms of our common Scotch Heather.

As with the foregoing, so with *E. vagans*. The big, sprawling, handsome Cornish Heath is presented in many forms, ranging from a poor, washy, creamy pink to the deep and imposing crimson-purple of *rubra* or *grandiflora*. *E. vagans* is a Heath for wide spaces, a robust grower and one easily satisfied. Though one of the last to bloom it will "carry-on" throughout August right into autumn and even on our dry, sun-beaten slopes the drought has to be very severe before this stalwart shows signs of surrender. One reason why *E. vagans* just escapes being as attractive as one imagines it ought to be is that the flowers of the spike die off in rings of rust as they open towards the tip. *E. multiflora* is of the same type as *vagans*, but it is more compact and more orderly in habit. The flower racemes are shorter and blunter and of a cheerful rosy-purple.

E. stricta, the hardy, erect, fuzzy-looking Corsican Heath, which will go up to 4ft. or more, is so distinct that it is not considered as showy as many others it is always effective by way of affording contrast, and it

fresh, lively green of its foliage, tipped with the rusty-red of the withered flowers, are among the most delightful objects of our winter gardens.

Rarest and most beautiful of all these, *E.*

AN EFFECTIVE MASSING OF VARIETIES OF LING (CALLUNA VULGARIS).

HERBACEOUS BORDERS?

A protest against a misleading term and notes on the advantages of the raised border.

HERBACEOUS? Perhaps, for the term seems to cover a multitude of sins, albeit invariably proving safe refuge to a good old friend of youthful days, long since gone where good old gardeners go. He was only to be momentarily nonplussed over some or other unrecognised hardy plant, and went to comfortably dispose of it as "one o' thim yarbaceous things." They totted up a big list, which, after many days, appears to have increased and further grown out and away beyond the orthodox interpretation of plants with annual tops and everlasting bottoms. Puzzled judges at a flower show, on one occasion at least, condemned the word as a trap for the unwary and a stumbling block to trip up both themselves and exhibitors. There was trouble over it then, and ever and anon there is trouble over it now, for, as then remarked, there are popular plants on the border line which leave openings for dispute. If the word were eliminated from our show schedules and perennial hardy plants, other than shrubs, substituted, such *contretemps* could scarcely arise.

The hardy flower border is, or should be, a joy for twelve months of the year, much in the way that my Lord Bacon (he of Shakespearean times), referring to the larger scale, said, "I doe take it in the Royall Ordering of Gardens there ought to be gardens for all the moneths of the yeare, in which, severally, Things in Beautie may then be in season." It is not uncommon nowadays to find borders to which the Elizabethan poet-gardener's notion may not inaptly apply, but not less common to see hardy flower borders suggesting how much they might at small expense be improved both in their formation and in their planting. As to formation, at no time of the year does the low-level, flat border give one a more uncomfortable feeling than during dull December, when it lies cold, stagnant and wet. There are many pretty well approaching that

condition, but few lifted bodily and boldly up as one under notice which is a full foot above the walk level. This has a retaining edging of rockery

A RAISED "HERBACEOUS" BORDER WITH ROCKERY EDGING CAN BE VERY EFFECTIVE.

stones, in this case got, for the carrying, from a local quarry at hand.

Quite recently in the very depths of winter there came from that border a good measure of that colour which Ruskin tells us is meant for the perpetual comfort and delight of the human heart. It came from bold tufts of *Iris stylosa*, both in its blue and white forms, from Christmas Roses, and from the brickground of low brick wall, from which *Chimonanthus fragrans* and *Lonicera fragrantissima*, the latter in a delightfully unkempt, wilful tangle, diffused their perfume on every beam of pale wintry sunshine. It was but recently, too, a *Ceanothus* added its heavenly blue, of which the Earl of Moira said, "This beautifull shrub thrives better in the open ground than in the house and is covered with flowers from July to December," and which he recorded in his copy of Hanbury's Gardening published in 1771. The border in question was remade during the dull season some twelve-month since, and seen now all is well established, one can say in garrulous old Pepys' words, "the which did please me most mightily." Herein is a combination of "yarbaceous" flowers with an alpine flora as an edging among the stones they love. A little later it will be an incomparable framing to a satisfying picture.

And more, for the lady who loves her garden, and, in her gardener's parlance, "loves to be pottering among the outside plants," says the working advantages over the all but flat and sometimes actually sunken border, apart from facilities afforded for inspection by visitors, and enhanced appearance of plants brought nearer to the eye, are so good that she contemplates the re-formation of some Rose beds on similar lines. That may be, or it may not be, for at the moment there is some opposition, rather felt than expressed, from that

man of the spade. Probably he thinks "the Missus" is mad; anyway, judging by pleasing results obtained in the lifting up of the hardy flower border to the height of a good foot above the walk level, there is method in the madness, and the conversion of ugly mounds far more than a foot high in the centre, falling away to the grass level, may too have as happy an ending, but *nous verrons*.

Dublin.

K.

CURIOUS PLANTS

Their fascination and some of their peculiarities.

THE fascination of the curious, rather than the beautiful, has a strong hold on many people, somewhat in the same way as in much modern art there is a quality that both attracts and repels. In one's childhood one did not see the beauty of *Antirrhinums*, but rather the fantastical likeness to an animal whose mouth would open and shut—they all had that charm, the colour did not matter. *Delytra spectabilis* was another nursery favourite with its similitude to a delightful fairy coach drawn by harnessed doves.

Later years bring an interest in legendary lore, or the medicinal uses of many of the garden favourites that possess qualities recognised or repudiated by the British Pharmaceutical Society. There are history and romance enough in the derivation of the names of many of our plants to carry the mind away to the far countries from which they were first obtained. Where and whence came the modest little plant bearing on each trefoil leaf a blood-stained spot? *Medicago Echinus*, or Calvary Clover, that growing beneath the Cross was stained with the blood of the Saviour, and carried the mark, so legend says, throughout the centuries.

Plants that contract on touch are many, and many, indeed, are the flowers that close their blossom when the sun goes in—to witness, the common weed, the little red *Pimpernel*, *Anagallis arvensis*; while the ordinary white Clover folds its leaves at sundown. But there are more plants that respond to the varying natural phenomena and cannot be classed as curious, but rather interesting.

Quite apart is the remarkable perennial, *Dic-tamnus Fraxinella*. Numerous people consider, when they have little or no knowledge of its character, that the name—the Burning Bush—applies to its colour; but this is very wide of the mark. The leaves are of a fresh, subdued green, the whole plant, both leaf and flower, low toned and unremarkable, scarcely sufficiently beautiful to include in a border but for the foil it makes to other plants. Its unusual aromatic scent is certainly an attraction, but unexplained appears to be the fact that in full sunlight, when the blossom is expanded, a lighted match placed within a few inches of the plant will ignite a flash of flame that flickers over the blossom, doing apparently no harm, but liberating a still more powerful scent. Probably there is some chemical cause for this little known fact; but for most people the interest of the unexplained is sufficient to earn it a place among plants that are beautiful and sufficiently understood to raise no question.

Adaptation to surroundings appears to be the reason *Drosera rotundifolia* is carnivorous. This, our native round-leaved Sundew, is only to be found on poor, boggy soil, where it has little to sustain life, and, therefore, nature has adapted itself and given it means of obtaining insect food. The leaves, covered with a honey-like substance, attract the unwary and are the death trap of many

THE GRANDEUR AND DISTINCTION OF EREMURUS HIMALAICUS.

diminutive insects. This tiny plant cannot compare with the Ceylon Fly-catcher, for instance, which is a quick-growing climbing plant whose curiously marked blossom is as much as 8 ins. or more across. Into its pouch-like throat insects

are attracted by a powerful smell, not unlike bad meat, and once they have passed into the centre of the flower they are hopelessly imprisoned, a network of fine hairs preventing their ever regaining freedom. M. B.

little attention with the pruning scissors. Many good judges consider the very different *S. Lindleyana* the most beautiful of all. It certainly is, when covered with its fluffy blossom, remarkably effective. Unfortunately it does not long remain at its best and its beauty is mainly on the plant. When cut, its feathery clusters compare unfavourably with the pearl-white sprays of *prunifolia*. Beautiful in a similar way, but less handsome than *Lindleyana*, is *S. discolor*, which flourishes in moderately dry soil where *S. Lindleyana* would hardly be a success. *S. arguta*, with arching sprays of white flowers produced before the leaves unfold, is another excellent kind.

So far we have been considering species suitable for the shrubbery, wild garden or herbaceous border, but there are several species which are admirably fitted for the rock garden. Such are the prostrate *S. decumbens*, which smothers itself in June with clusters of white blossoms. A native

A SELECTION OF SPIRÆAS

Differing enormously in appearance and habit of growth, some being shrubby and others herbaceous, the Spiræas and nearly related Astilbes are invaluable in gardens where the soil is naturally damp.

AMONG the herbaceous Spiræas, using the word loosely to include the Astilbes, the newer pink forms which have resulted from crossing the tall purple Astilbe *Davidii* with *A. japonica* and Spiræa *astilboides* have lately claimed much attention. They are almost all beautiful and easy plants for a moist, cool border, or for forcing under glass, but it is to be feared that they have in our gardens largely ousted plants such as *S. palmata* or *S. Aruncus*, which, as garden plants, have far more merit. In moist, half-shady ground, by poolside or in the wild garden, *S. palmata* grows with almost sub-tropical grandeur, while the crowded heads of rich carmine-rose form a spectacle not soon forgotten. To see this plant in a dry, rather sun-parched border, as one sometimes does, its leaves small and wilting, the growth insignificant and the flower-heads discoloured, is, to a gardener, one of the saddest sights imaginable.

Spiræa Aruncus is one of the stateliest and most accommodating herbaceous plants we have. It will furnish admirably places on the north side of buildings where few things will grow. It will luxuriate, when once established, among shrubs in a mixed shrubbery where it is a matter for wonderment how it obtains its moisture. It is quite at home in a light soil, provided it is afforded good cultivation, yet it will grow and flourish in absolute brick-earth. It is equally tolerant of sun and shade. It has a majesty of growth which few herbaceous plants can rival. Of very few plants can as much be said, yet there are many gardens to-day in which this beautiful plant cannot be found. One wonders why. The cut-leaved form, *S. A. Kneiffi*, is quite useful and beautiful, but it lacks the real grandeur of the typical plant.

For open spaces in the wild garden or bog garden the large growing *S. kamtschatica*, so reminiscent of our native Meadowsweet (*Spiræa Ulmaria*), is exceedingly useful. Often listed as *S. gigantea*, it has a form called elegans with pale pink flowers. Both these attain, under suitable conditions, a height of 6 ft. or more.

Spiræa (Astilbe) japonica and *S. astilboides* and their varieties are largely grown for forcing under glass, but they are excellent foreground plants for massing in a damp corner of the wild garden.

Why is it, one wonders, that while many gardeners with naturally damp soil expend much money and energy in their efforts to drain it, others with bone-dry soil dissipate, if possible, more energy and wealth in making bog and water gardens? It would seem to show the essential contrariness of human nature, but perhaps it would be more charitable to suppose that it were merely a sense of discipline which sets each and all of us busy overcoming difficulties. Two other herbaceous species call for mention and then we will consider the shrubby kinds. The two species in mind are *S. Filipendula*, which is a singularly neat-growing and easy native species for a cool border, with foliage which is useful for arranging with

many kinds of cut-flowers; and *Astilbe grandis*, of which the towering white spikes and handsome foliage make a wide appeal. There is a double variety of *S. Filipendula* which is singularly handsome, but surprisingly little seen

ONE OF THE MOST EFFECTIVE OF THE SHRUBBY SPIRÆAS, *S. LINDLEYANA*,

No attempt has been made to make the foregoing list a catalogue of species or varieties; rather an attempt has been made to call attention to some beautiful but neglected forms.

The name of the shrubby Spiræas is legion, but in probably no genus of shrubby plants are there so many useless forms in commerce. This notwithstanding, some of the species and varieties are supremely beautiful. There is the dwarf and spreading *S. Bumalda* with that supreme variety, *S. Anthony Waterer*. An excellent plant the last for the front of a shrubbery, but to obtain the best effects the old wood should be removed each season and the young wood shortened considerably. *Spiræa callosa* is, at any rate, in the writer's opinion, of little value. *S. prunifolia* fl-pl., with pearly white rosettes, is probably the most beautiful of all. It has an arching habit of growth which too close pruning must destroy. *S. Van Houttei* (*cantonensis* × *trilobata*) is more ordinary in appearance, but yet very beautiful. It needs but

of the Tyrol, the most particular may include it in his alpine collection. It spreads by means of underground "wires," so is easily propagated. Other desirable alpines are *S. Hacquetii*, *S. caespitosa* and *S. pectinata*, the two last mentioned from the mountain slopes of the New World. Different entirely in character—larger growing but very desirable in character for the fair-sized rock garden—is *S. Thunbergii*. This is beautiful in flower and, like many Japanese shrubs, extraordinarily beautiful in autumn when the leaves take on tints of old rose and crimson.

Before leaving a very diversified and interesting race of plants, it may be well to point out that because such plants need abundant moisture it does not by any means follow that they like stagnant moisture such as is too often found in bog land. As a matter of fact, the shrubby kinds in particular like a fairly sweet soil, but one which does not become over-dry during the growing period.

SAINT DOROTHEA

The frontispiece of a rare old flower book of 1616 suggested a walk down the Avenue of Garden Saints. Its result.

GARDENING is far more than ever a "super goose-foot" in the number of avenues which radiate from it and down which its votaries may wander with interest and pleasure. One of these is labelled Garden Saints. It is probably one of the least explored, if I may take

THE GATEWAY TO THE PAST!

as a guide the answers given by gardeners to my question, "Who was St. Dorothea?" So far the invariable reply has been, "I am afraid I do not know." I must confess I did not know myself until a very scarce old flower book came into my possession—"Le Jardin d'Hyver," by Jean Francau de Lestocquoy, published at Douay in 1616. On the frontispiece are two figures, both bearing the martyr's palm. The one on the left is a woman, St. Dorothee, and that on the right is a man, St. Theophile. Above them is an angel appearing out of the Glory, who is handing to St. Dorothea a garland of Roses and to her companion a basket of flowers. Why did the author introduce these two figures on his frontispiece? Sometimes in these ancient books there is a poem called "The Mind of the Frontispiece"—as, for example, in John Rea's "Flora, Ceres and Pomona"—which lets us into the secret; but no such writing is attached to "Le Jardin d'Hyver," so the would-be interpreter must depend upon his knowledge or research if the enigma is to be solved. One remembered that Columella, in his tenth book on Roman Husbandry, treats "Of the Culture of Gardens" and introduces us in Priapus to the ancient progenitor of the modern scarecrow—or, rather, perhaps, spring-

gun:
"Him, in the middle of thy garden, place,
And to him, as its guardian, homage pay,
That with his monstrous parts he may deter
The plundring boy; and with his threatening
scythe,
The robber from intended rapine keep."

But, of course, one could not expect to find Christian martyrs there. "Try Batty Langley," said a friend. He wrote when statues and busts were "all the go," and in his "New Principles of Gardening" he gives a long list of those which are appropriate to the different parts of a "beautiful Rural Garden." For open lawns and large centres: Mars, Jupiter, Apollo, Euterpe and so on. For woods and groves: Ceres, Flora, Echo, Philomela and others. For canals, basins and fish-ponds: Neptune and other gods and goddesses. I went through the whole list and found they were a heathen crowd. There was not a Christian among them. Clearly one must search elsewhere for Dorothea.

Now, whatever truth there may be in the saying that everything comes to him who waits, it would appear to be a more certain truth still that the open and keen eye gets more than it expects. For a long time now I have been keeping my eyes open, picking up one little bit of information here and another bit there as I kept wandering down the Avenue of Garden Saints. I have now found out that Dorothea was a lady of noble birth born at Caesarea, who was condemned by the Roman Governor, Fabricius, to be executed because she refused to sacrifice to his gods. On her way to the place of execution a lawyer, whose hand she had refused because he was a heathen, begged her to prove the truth of her stories of the Heavenly Paradise by sending him some of the flowers and fruits from her Bridegroom's garden:

"Now as she died the scoffing lawyer stood
Among his comrades, jesting at the gift
The Maiden promised. But when now they sat
Feasting, around them gilded images
Of the false gods, taking no care or thought
For what had been, the torture and the pain,

Lo! suddenly a heavenly presence showed,
From whence he knew not, fair, with shining face,
And locks of gold, and eyes as blue as Heaven,
And in his hand a basket with the fruits
And flowers of Paradise, who spake no word
But 'Dorothea sends them and she goes
Before thee to the garden whence they came,
And doth await thee there' and having said
Vanished as he had come."

"Then cried they all that saw these things, and said

It was God's doing, and was marvellous,
And in brief while, this knight Theophilus
Is waxen full of faith, and witnesseth
Before the King of God and love and death,
For which the king bade hang him presently.
A gallows of a goodly piece of tree
This Gabalus hath made to hang him on.
Forth of this world to Theophile is gone
With a wried neck, God give us better fare
Than his that hath a twisted throat to wear;
For truly for his love God hath him brought
There where his heavy body grieves him nought
Nor all the people plucking at his feet;
But in his face his lady's face is sweet,
And through his lips her kissing lips are gone:
God send him peace, and joy of such an one."

Readers will recognise that I have, as it were, jig-sawed the last part of the tale. Both the rhythm and the outlook proclaim the extracts are from two writers, and in truth they are, and this is done purposely to show that the mythical and mystical tale of this virgin martyr has appealed to men of such diversity of outlook and method as Lewis Morris and Algernon Charles Swinburne. They have each of them made the Saint the subject of a poem of striking similarity, yet with

THE MARTYRDOM OF SAINT DOROTHEA, AS PICTURED BY BURNE-JONES.

no less divergent details; as did Massinger (1585-1638) in his famous tragedy of "The Virgin Martyr," who, like them, introduced still further differences, inasmuch as one Antonius, son of Fabricius, is made "the lover of the young girl whose last prayer for him is that the affection in which he languishes to death may be changed to the love of heaven." Thus Dorothea is sung in modern days; but her fame is of long standing. In a Breviary of 1321 we get these lines:

"Paradisi de veridiso
Rosas mittis notario
Quem mortis cum salario
Cœli jungis sacerario . . ."

which is thus translated in Mrs. Arthur Bell's "Lives and Legends of the Great Hermits and Fathers of the Church, with other Contemporary Saints":

"From the green fields of Paradise
Roses to the lawyer dost thou send
Where by him thou shalt be joined
When he, too, the reward of death hath won."

In pre-Reformation times her figure would frequently be seen on English rood-lofts. Those of North Elmham, Blofield, Yaxley, Westhall, Trimmingham and Walpole St. Peter are samples of a widespread popularity which elsewhere took a more secular form; for in Flanders, after the upheaval and upset of the time of the mad Tulip mania, when legitimate dealers in bulbs were all at sixes and sevens and a general spirit of distrust was visible in their private selling; "because this could not be done without Animosities thereupon the Flemish Florists erected a Fraternity in the Cities; and took St. Dorothea to be their Patroness and the Syndicus to be Judge of the Differences, that might arise by their Truckering; and he to add more Authority to it called in four of the Chief of the Brotherhood and this was the Occasion of the sweet Conversation of the Brothers and brought them into great esteem. The Dutch keep in this Matter another Rule; they meet together on a certain Day, when tulips are in their full bloom and choose after having seen the chief Gardens of the Florists, and taken a friendly and frugal dinner together, one of the Company to be Judge of the Differences that might arise about Flowers in the Year." This is quite an idyllic picture. Alas! the old order has changed, giving place to new. On going about Haarlem, Hillegoom and elsewhere to see the Darwin, Cottage and Breeder Tulips in bloom I have had more than a hint not to bring a Dutch friend with me, and I have found to my cost that the frugal fare has developed as often as not into a big champagne lunch!

St. Dorothea suffered martyrdom, after having been stretched on the rack and her flesh torn with pincers, on February 6, 311. Ever since her festival has been kept on that day, and she has been regarded for a very long time as the Patroness of Gardeners. I can only suppose the Puritanical spirit that prevailed all through the eighteenth and nineteenth centuries acted as a silent but relentless veto upon the introduction into English gardens of any statue that in any way savoured of "Popery." As it was in the days when Hentzner and his young German pupil visited Nonsuch, Theobalds and Hampton Court in the reign of good Queen Bess, so it is now. But why should this be? If there is anything in the contention of a Batty Langley or a Wheatley, that the appropriate introduction of the statue of a well known subject of mythology, history, poetry or tradition may animate or dignify a scene, and so stir up feelings of sympathy in the heart of the beholder, surely for those who use their gardens as a resting place, "far from the busy hum of men," or as a

refreshment for their jaded spirits, might find strength and encouragement in the contemplation of a Dorothea. She is represented in various ways. Sometimes with a basket of fruit and flowers, one in either hand; sometimes with a basket of fruit and a book; sometimes with a basket of fruit and a palm; now crowned with flowers; now with Roses in her lap; and now offering flowers to the Holy Child. Curiously enough, she is the Patron Saint of young lovers

and brewers, a title which, however, she divides with Saints Adrian and Amand. The origin of this latter honour I have failed to discover. As I still hope to make excursions down the Avenue of Garden Saints, perhaps some day I may know. For permission to reproduce the plate from "Great Hermits and Martyrs of the Church," of the Martyrdom of Saint Dorothea as portrayed by Burne-Jones, I am indebted to Messrs George Bell and Sons, the publishers. JOSEPH JACOB.

"PRICKING OFF" AND ITS UTILITY

The writer considers the advantages and disadvantages of an indispensable operation.

THIS is an operation frequently practised in horticulture. The *raison d'être* for the practice being the wider spacing of young plants grown in the seed-bed which have become crowded and, in consequence, rob each other of light and air necessary for their normal development. The operation dispenses with the need for sowing seeds where the plants are to grow, a great convenience for many obvious reasons. It permits the sowing of seed to be made in smaller spaces, and gives one the freedom to choose and dispose of it under conditions the most favourable to the future well-being of the seedlings and young plants. Also the care necessary at this period can be more readily accorded to them.

It goes without saying that one can by this method obtain a better "braird" and the young plants will be more vigorous. Moreover, it is therefore possible to gain time and to procure a crop earlier, as preparation can be undertaken before the temperature of the air or soil be propitious for the vegetable, fruit or flower one contemplates growing. Or it may be, as in the case of hardy open-air growing plants, that the ground is not ready to receive them.

Again, in "pricking off" one ruptures the main or tap-root, breaking off its first ramifications and thus favouring the formation of root hairs, which renders less perilous a further transplantation. There are, then, evidently many practical advantages which in themselves justify the operation.

Since it is only by viewing both sides of a question that a true perspective can be obtained, let us consider "pricking off" and its influence on the growth of plants. We have hitherto considered the advantages gained by doing this work, but that it will always be beneficial to the plant to practise it is a very debatable point.

It is freely admitted that the breaking off of the tap-root and consequent encouragement of the emission of numerous small roots exercises a happy influence on the growth of the plant.

It has been proved by extensive trial that from sowings made in the open ground the earliest and heaviest harvests were gathered from crops not "pricked off." The weight of plants of the same variety from a like area in a given period submitted to "pricking off" has been much less in quantity and later in attaining maturity. The effect on the plant is that, deprived by the "drawing" of their extreme radicles and of their piliferous layer, they cannot, despite repeated waterings, maintain themselves in the state of turgescence necessary to their continued development. Nay, more, they exhaust themselves, for, their assimilative activity having been so much reduced, they are constrained to live at the expense of their own substance. This they must utilise in the reconstruction of their radicular and organic

system. From this we may deduce that "pricking off" or transplanting occasions an arrestation of the growth of a vegetable. This check will be intensified, according as the circumstances are

PRICKING OFF ANTIRRHINUMS.

This has been left over-ong—the plants are "drawn."

PRICKING OFF HERBACEOUS CALCEOLARIAS.

more or less favourable to an active transpiration. The conditions favouring active transpiration are a dry and agitated atmosphere combined with a high temperature in an exposed situation. It follows that the plants will suffer less from the operation if the air is humid with a relatively low temperature on a dull day. Transpiration also will be greater in proportion to the age of the plants and the consequently greater expanse of surface foliage. As an aside, this may explain why as journeymen gardeners we were instructed—with no explanation as to the wherefore—to "lift" them carefully with a good ball of soil attached, afterwards affording a copious watering and shading if necessary so as to limit as much as possible the check given in transplanting.

Many gardeners, without having a very clear idea as to why they do it, take advantage of this retarding effect caused by pricking off or transplanting. In late autumn if spring Cabbages are

growing too freely and making succulent growth not calculated to resist the vigours of winter, he partly lifts them with a fork—firming by treading afterwards—to check them. It may, on the other hand, be a young fruit tree planted loosely in over-rich soil making long and unfruitful growth which requires to be "checked" for its own and its owner's profit. These and many other instances

of a similar kind will occur to the minds of observant gardeners.

From a survey of the pros and cons the conclusion to my mind is that the greatest benefits and advantages to be derived from pricking off are to be obtained when the work is done in early spring or autumn. If it cannot be done just at the right time, better too soon than too late.

DEANSTON.

THE CULTIVATION OF ARUMS

The Arum is widely cultivated, but in private gardens is seldom grown to best advantage. Follow clear notes on its treatment throughout the year.

EXAMINATION of some standard works on horticulture reveals a remarkable lack of information concerning the culture of the Arum Lily. Having grown this superb flower successfully for upwards of twenty years, the writer feels that his experience may be helpful to other growers or intending growers. Arums can be used satisfactorily for indoor decoration following Chrysanthemums, which seldom last into the New Year; moreover, they are most acceptable for Christmas decoration in churches and public halls. In addition they can be used for sundry other purposes, wreaths, bouquets and floral designs.

The means of propagation is by lateral growths, which are small rhizomes developing on all sides of the main rhizome. During August the largest of these lateral rhizomes are split off from the parent plant and potted up into 7in. pots, three being allotted to each pot. The ideal soil consists

of a good mixture of leaf mould and fibrous loam at the rate of one to three. The best loam to use is that obtained from spent Melon beds, and it should be well decomposed. Half fill the pots with soil; place the rhizomes on this, and fill to within an inch of the top, pressing the soil moderately firmly around them. The crowns of the rhizomes should be about $\frac{1}{2}$ in. below the surface of the soil. The pots should now be stood in partial shade for about a fortnight, after which they can be removed into full sunlight, where they are allowed to remain until the approach of frost. During this period they should be copiously watered. Regularly, once per week, they should receive an application of manure water obtained in the following manner: Equal parts of soot and cow or sheep manure are mixed into a paste with a little water; one bucketful of this mixture is placed in a tub or other suitable receptacle and twenty gallons of water added. Apply this liquid manure at half strength through-

out the whole of the growing season. By the time they are taken indoors in about October the plants should have filled the pots with roots. The greenhouse wherein they are now placed should be heated, the range of temperature being from 55° F. by night to 65° F. by day, air being admitted on all favourable occasions. These temperatures should be maintained throughout the growing season until mid-April, when the plants can be taken out of doors, placed in partial shade, and protected from late frosts until the middle of May, after which they can be put into their summer quarters.

The summer quarters most suitable for Arums consist of a trench 18ins. wide and 18ins. deep. The bottom 6ins. of this should be filled with well decayed manure, a further 6ins. of soil should be added and the two well mixed. The "Lilies" should now be taken out of their pots, the crocks removed and the plants stood in the trench from 4ins. to 6ins. apart. The surplus soil from preparing the trench should stand on either side as in the manner of a prepared Celery trench. This soil is now to be filled in around the Lilies and consolidated by being lightly trodden. The plants should next receive a heavy watering, which will complete consolidation; after this they will require no further attention until growth recommences. During this period the foliage remains active, manufacturing food which is stored in the rhizomes. After a while their activity diminishes and the leaves turn yellow and die down over the crown; when quite dead they should be carefully removed. In late July or early August new green leaves will be thrust up; this marks the commencement of a new season of growth, which should be allowed to go on in the bed until about the second

CORRESPONDENCE

ROMAN HYACINTHS FOR CHRISTMAS.

IN growing flowers for Christmas I invariably pot up one or two bowls of Roman Hyacinths. For an amateur who has no greenhouse they are the most accommodating of all early forcing bulbs, as at no stage of their growth do they require a high temperature to bring them into flower by Christmas. I usually grow them in fibre in bowls without drainage, putting them into the bowls about the last week in August or early September. The accompanying illustration is of a bowl planted September 14 and photographed December 24, 1921. The fibre needs to be made just sufficiently moist to handle freely without the moisture squeezing out when a handful is pressed. A little crushed charcoal placed in the bottom of the bowl prevents the fibre going sour. Place fibre in the bowl to a depth of about 2 ins., on which place the bulbs, then fill up the bowl just covering the bulbs, but do not press the fibre in too tightly. Place them in a cold frame, or place out in the open, and when in position give them a good watering through a rose. They then require no further watering until taken indoors. Then cover the bowls with fibre to a depth of about 2 ins. If the weather is mild it is better not to put any further covering on them, but in case of severe frost it is better if in frames to put on the lights; or if outdoors, cover with mats, sacks, or anything that may be available. When top growth is advanced about 1 in. they should be uncovered and given a good soaking, draining off any surplus water by tilting them. The bowls may either be left in the cold frame with the lights on, or put into a light, airy window where there is a regular temperature of about 50° to 55°. If kept at a higher temperature they will flower before Christmas. If the outdoor temperature is low and the growth is not sufficiently rapid, move them into a greenhouse or a warmer window. Nine-tenths of the failure to flower bulbs successfully in bowls is due to allowing them at some stage of their growth to become root dry. That is fatal to success, as once they are allowed to become dry, no amount of watering afterwards will cause them to recover. There is one other point that should be noted. If the bulbs are plunged outdoors with a covering of 2 ins. to 3 ins. of fibre, and there is an excessive rainfall, something should be put over them to prevent their getting too much wet, as if they get an excess of water before root growth is fully

advanced, it is almost as injurious as allowing them to get dry. The latter applies to all bulbs which are grown in fibre. Mice are partial to Tulips and Crocus, and a look out should always be kept for their depredations. I have never yet failed

A FINE BOWL OF ROMAN HYACINTHS AT CHRISTMAS-TIME.

over a number of years to have good Romans at Christmas.—G. W. L.

SOME PYRENEAN ANDROSACES.

LAST year, being in the Pyrenees, I made enquiries about two different families of plants: the Saxifrages (particularly those of the *Dactyloides* section) and Androsaces. I purpose now to write of these latter treasures, *Androsace Lagerri*: The "Index Kewensis," like many botanists, considers this only a form of *A. carnea*. Having grown it for forty-nine years, I know it well. Everyone who grows alpins knows that there are chalk-loving and chalk-hating forms. *A. carnea* is lime hating and *A. Lagerri* lime loving. The one is, of course, the form from the chalk; the other from neutral formations. *A. carnea* grows as little very dark-leaved bushes not exceeding 2 ins. across. *A. Lagerri* forms very large tufts, sometimes a foot broad, very dwarf and of clear colour. Its leaves are thin, narrower than those of *carnea*, never reddish, but always of a light green and very pointed. The leaves are never glandular, as are those of *carnea*, but

week in September, when the plants should be taken up and repotted into their flowering pots. Lifting should be carefully performed and the soil adhering to the roots should be moved with the plants to the potting shed. Here all the exhausted soil, which can be easily recognised by the line of previous potting, is removed by means of a pointed stick. It will come away readily. The gin pots used should be clean and crocked and the crocks covered with an inch or so of friable decayed manure. Potting soil as previously described is again used. It should be worked well in around the roots and crown. The plants are now placed in partial shade and kept syringed or watered overhead with pot and rose, twice daily to prevent wilting. The next operation is staking, which is most satisfactorily performed with canes and raffia.

After about a week they can be removed to full sunlight to harden-up prior to being taken into a cool greenhouse. Here they remain until frosty weather, when they are removed to the heated greenhouse, where the temperatures as advocated for the first season's growth are again maintained; within a fortnight after this flower buds should appear. The flowering period should extend over about six months; that is, until the end of April. This stock of plants will last for about seven years, by which time the rhizomes become elongated so as to render satisfactory potting difficult, therefore it is necessary to remove about 2 ins. from the lower end of each rhizome with a sharp knife. It has been found advisable to retain a number of the young lateral rhizomes, since these throw up foliage which can be used for decorative purposes, as, for example, with Roman Hyacinths and the like.

The chief insect pests of the *Arum* are aphid and red spider, the latter only occurring when the plants are grown in too high a temperature and when the atmosphere is too dry. Aphid can be kept in check by fumigating with any of the usual proprietary fumigants or by a soap and nicotine spray. A very efficient spray is made with soft water; it contains soft soap 1.6 per cent. and nicotine .05 per cent.

The most useful species is undoubtedly *Richardia africana*, sometimes called *athiopica*, the white *Arum*. According to Robinson ("The English Flower Garden"), this variety "was first introduced into Europe from South Africa in 1687." Referring to its growth in the British Isles he states, "In some parts of this country, for instance, Cornwall, it has become naturalised in shallow water, spreading and flowering with the same freedom as in the ditches and swamps of the Cape." In Gloucestershire it flowers well and maintains its vitality when planted in pond mud, around the edges of fountains and ponds, and winters quite satisfactorily. This species is undoubtedly the best for greenhouse culture. Another good species is *Richardia hastata*, the Yellow Calla. It is smaller than the white *Arum*, with which it affords a pleasing contrast. Hooper ("Gardening Guide," 1883) describes it as follows: "Its flowers are of similar form (*i.e.*, to the white *Arum*), and of a beautiful soft yellow colour, the throat being purple. It is hardy, and out of doors comes a deeper colour than under glass, but it nevertheless makes a beautiful pot plant." He recommends that "the soil used for it should be light, almost sandy."

Where *Arums* are cultivated along the lines herein suggested, with suitable modifications according to local conditions, success and satisfaction are insured.

The illustration on page 32 shows it luxuriating in damp ground in the Nilgiri hills (India); but it makes almost as fine a picture in shallow water by an English lake-side. WILLIAM H. MILES

ciliate with short and single hairs, instead of which carnea has one or more bifurcate hairs, very long. But the chief character is that the stalk is accrescent and, being at first very short, grows as the flowers expand until sometimes 4ins. long. The plant is of easier culture than carnea and forms in the rock garden large clumps of pinkish-rose flowers, very shortly stalked to begin with, as already explained, but lengthening in a wonderful way. In the months of March and April it is the most brilliant flower in the garden. Another very fine *Androsace* is *ciliata*. This is exclusively Pyrenean. It grows on the cliffs of the high peaks above 5,500ft. Near to our alpine glacialis, it has much bigger flowers and forms dense zin. to 4in. cushion-like tufts, which are, from June to August, covered with deep rose, quite sessile flowers. *Androsace cylindrica* is another very rare kind, which grows only on a very small area in walls supporting the path at the Cirque de Gavarnie. Near to *pubescens*, it differs from it by its sub-frutescent stems and its very small, reflexed, whitish green leaves. *A. hirtella* is a form of it growing under the same conditions, but with long hairs, either single or divided. The flowers of both are white and sessile, so form dense patches. They both require a south wall or a crevice in a dry rockery. *Androsace pyrenaica* is a rather rare plant growing between siliceous or granitic gravels or rocks at the highest altitudes (always above 6,700ft.). It is near our *argentea*, but still denser and more "cushiony," and the tufts of very old stems very close together are extremely curious to see. It grows freely in England, as I have friends there who have sent me beautiful photographs of it taken in their rockeries. It seems even to prosper better in some English gardens than in the high Pyrenees. It likes, however, the perpendicular position, as does *Saxifraga longifolia* (that is, it should be planted horizontally). *Androsace villosa* forms, in some limestone cliffs of the Pyrenees, immense carpets of flowers from May to July. It is particularly rich in the neighbourhood of the Pic du Midi and is often mixed with *Laggeri* and even with *Vitaliana*. The most wonderful thing I have seen in the Western Pyrenees is *Soldanella villosa* (Darracq). It is near to *montana*, though larger in leaf and flower; but it has the stem and base of the leaf quite hairy. I was glad to find the very curious and rare *Saxifraga Clusii*, which grows on the walls near the Pic du Midi, and in damp underwoods, here and there. *Lilium pyrenaicum*, which is, nowadays, becoming rare.—H. CORREYON, *Floraire, Geneva*.

BEGONIA NARCISSIFLORA.

IN the issue of THE GARDEN dated January 7 it is stated that "few readers will this year succeed in obtaining the new narcissiflora strain, but those in search of novelty may, with confidence, try . . ." We beg to point out that we are offering seed and tubers of this novel type of *Begonia*. The seed was saved in our own nurseries, and the tubers were grown from selected seedlings, all of which flowered with us last season. We also beg to point out that the photograph of this *Begonia* which appeared in THE GARDEN some little time ago was taken in our nursery—DOBBIE AND CO., LIMITED.

Our correspondent who sent the picture reproduced in our issue of October 22 last, in reply to an enquiry, stated that he understood that the well known Edinburgh house would not be able to offer this strain this season, hence the note Messrs. Dobbie refer to. He mentioned at the same time another firm who had a little seed to offer. We are glad to hear that Messrs. Dobbie can supply seeds and tubers, and welcome the

opportunity of correcting an unintentionally erroneous statement.—Ed.]

IRIS TINGITANA.

OF all the bulbous species of *Iris*, both for beauty and utility I know of none that can compare with *tingitana*. Here, on Christmas Day, we were able to cut beautiful spikes from a foot to 18ins. long, with grey, glistening foliage, surmounted by Orchid-like flowers of the richest blue with tangerine markings. This species does not seem to be in general commerce, as here, in Liverpool, with its many high-class florists' shops, we failed to notice a single flower displayed in any of the windows at the time when ours were in their full glory. Of course, *I. reticulata*, that

strongly scented flowers were crossed, and out of a progeny of 3,500, five only were clove scented. Having noted these facts, let us turn for a moment to a reference made in another part of the book to Mendel's laws—Professor Mendel, as he is erroneously styled. Mr. Douglas wishes that Mendel had taken the Carnation for his experiments, but a knowledge of the work done by the observant monk and the bases on which his theories became laws makes it clear that the Carnation was not a subject that would have helped him in his surmises. The complicated crossing and interbreeding that have taken place through many generations have too thoroughly erased the elemental factors, dominant and recessive, which build up the simple hybrid—the first generation

IRIS TINGITANA, FLOWERING OUTDOORS IN MAY.

little gem with its subtle scent, peeped out here and there, but it is a pigmy in comparison with *tingitana*, whose noble spikes when arranged in tall glasses were the admiration of all who saw them here. I should be pleased to give the readers of THE GARDEN the cultural details which led up to our success with this fine monocotyledon, if you so desire.—R. MCHARDY, *West Doby*.

[Particulars of the successful cultivation of this charming flower would be of interest to many readers.—Ed.]

A CORRECTION.

ON page 21 of THE GARDEN a correspondent, J. W. Brigstock, Wisbech, says that, on page 630, "Somers expresses his appreciation of the Dutch bulbs ordered direct from Holland." Will you permit me to say that, so far, I have written nothing whatever on this subject.—SOMERS.

BORDER CARNATIONS.

I HAVE been reading Mr. Douglas's book on "Border Carnations and Cloves," published by "Country Life," Limited, and its perusal stirs many thoughts regarding the cultivation of these plants. I was particularly struck with the author's experience of the two crosses detailed. In the former of these he crossed two yellow selfs, Daffodil and Germania, and out of 2,000 resulting plants not one was a yellow self! In the latter, two

offspring. Without these factors Mendel's principles would, in all probability, have been still-born; but all that apart, let us now see the Mendelian interest attaching to Mr. Douglas's experimental crosses. His results seem to emphasise two pronouncedly recessive characters in the flowers of the modern Border Carnations, viz., yellow pigmentation and clove scent. If that can be taken for granted, it would at least mark some small progress towards certainty in the hybridisers' work, and it is a pity Mr. Douglas did not go further in his experiments with these seedlings. In Mendel's law of Segregation and Purity it is shown that if second generation dominants are self fertilised they will throw 75 per cent. dominants and 25 per cent. recessives, but—and here is the important point—if these recessives are self fertilised and a third generation formed of their progeny, these are true recessives without a trace of reversion to the dominant characters of their parents, just as pure dominants breed pure. It would have been highly interesting to know what results would have accrued from the self fertilisation of these seedlings, and it is just possible the recessive characters would have reasserted themselves after skipping a generation. Mr. Douglas makes the somewhat staggering statement that Carnations can now be had in every known colour; but, even leaving out the obvious exceptions such as the blue of *Gentiana Verna* or the green of *Isia viridiflora*, we are woefully weak in all shades of purple, heliotrope and lavender, let catalogues

speak as they will. Again, there is no buff Carnation of the lovely shades seen in some of the *Gladiolus Primulinus* hybrids, such as *Cassandra* and *Topaz*; no saffron, no true violet; many of the orange combination colours are wanting, those grading into the vermilion and salmon shades for instance. Many shades of red are still unknown to the Carnation, and who has ever seen in the Carnation world that wondrous ethereal tint of *Gladiolus Byron L. Smith*? No; I have more hope for the future of the Border Carnation than to think we have reached finality in colour, and I do not think growing for new varieties would be half so interesting if "every known colour" were already on the palette.

While I am on the tack of destructive criticism I might point out a debatable subject which must be of great interest to Carnation growers. Touching on diseases, Mr. Douglas makes certain remarks about rust which I fear many practical growers will find at variance with their own experience. For instance, he likens rust to "a rash caused by overeating," and blames overdoses of potash administered through the agency of burnt garden rubbish as a frequent cause. Now, in the case of two well known and successful growers of Carnations the result seems to be far from that indicated by the author. In the former instance a moderately rich compost is used, but what seems to me to be an excessive proportion of burnt refuse is employed every year, although the proportions of soil ingredients are varied each season. In the second case, no animal manure is used at all, the only stimulants employed being a sprinkling of bone-meal and a liberal dressing of burnt wood-ash from the garden bonfire. Now, though I have seen the plants in these two collections at different periods of the year I have never seen a spot of rust on the foliage. Our own experience is similar; last year we potted a section of our plants in a control compost of sound, fibrous loam, very slightly enriched with added manures. Five other sections were potted in five different soils, varying in degrees of fertility—some rich in phosphates, some in potash, and some in nitrates. At that time, pending the completion of new Carnation premises, we were growing our plants under adverse conditions and we had more rust than we bargained for, but careful examination did not reveal any one compost more blameworthy than another, the control compost giving perhaps slightly, but very slightly, the most satisfactory results in this respect, though not the best flowers.

I am glad Mr. Douglas makes a strong point of the hardness of the Border Carnations, and of the fact that any soil can be made to grow them well, whether light or heavy. It is quite extraordinary how insistent certain people are that the Carnation will not grow in their gardens. As a rule, these decisions are second-hand, and frequently denote other interests on the part of the gardeners of the establishments in question. I would go further than Mr. Douglas and say that the *Picotees* are also admirable for bedding, at least in the South and Midland districts. Such varieties as *Cheam*, *Santa Claus*, *Her Majesty*, *Mrs. J. J. Keen* and *Margaret Lennox* make extremely fine plants even in exposed localities and on heavy soil.—J. L. GIBSON, *Crawley Down, Sussex*.

[From a Mendelian standpoint the difficulty with the Carnation would seem to be rather a multiplicity of probably overlapping factors which have, so far, not been disentangled, rather than excessive cross-breeding. The garden Pea, for instance, or the Sweet Pea, have been long in cultivation, but they both illustrate admirably Mendel's Law because their factors are comparatively few and simple.—ED.]

A NATIONAL DAFFODIL SOCIETY?

MR. JACOB'S contribution of December 31 to this discussion repeats clearly what the other advocates—or may I call them agitators?—have propounded as the work of the said Society. Let me repeat his summary with what appear very obvious comments:

(1) Holding of two shows a year, one in London and one in Birmingham. These we have already. (2) Publishing a Year-book. This we have not got, but it could be had now if subscribers enough were forthcoming; but I should add that the cost under present conditions would be prohibitive, as anyone knows who is at all concerned with printing and publishing. (3) A forced or pot-grown show in March. This we have already. (4) A London dry bulb show in August. This we have already; an affair of small attendance, as it must always be. (5) Deputations to local shows. This we have had and can have from our present *personnel*. (6) Any necessary Daffodil legislation. This is fairly vague, but would seem to be covered by the functions of the R.H.S. Narcissus Committee. (7) The united support of traders and amateurs, both of whom must be catered for. Here is some confusion of thought between the maintenance of such a Society by the people affected and the Society's allurements to obtain their maintenance. This clause is simply a proviso that the Society shall be a success all round.

Mr. Jacob now adds that there would have to be a London organisation and a Birmingham one to carry out the idea of two annual shows, and that it seems to him silly to scrap the organisation connected with the latter. Now I must ask sensible folk to consider the elaboration of fussy super-officialism that it is proposed to heap upon this modest flower—a National Society with its officers and Committee, the large R.H.S. Narcissus Committee, a London organisation, a Birmingham organisation and the existing Birmingham Committee! I have received a proposal, among the letters which this affair has brought upon me, that the R.H.S. Committee, *with the addition of other names*, and the Birmingham Committee shall be amalgamated! The R.H.S. Committee alone is unwieldy enough and twice too big for efficiency.

And all this machinery for what provable advantage over what we have? So far as I have kept count, *every* trading firm and *every* amateur grower with a flower worth notice attends the existing shows. Who are the people who would hypothetically flock to a National Show? A correspondent writes that what we want is a *big* London show, and he instances the bigness of the National Sweet Pea Show. Those who are pushing this concern have curiously overlooked an obvious factor. There is this abiding difference between the Daffodil's popularity and that of the Sweet Pea, the Rose, the Chrysanthemum and other quickly propagated flowers: the most attractive and newest of these comes within everyone's reach speedily and for a small sum. A new Daffodil cannot be handled at all under ten years from the seed and must always be rare and beyond the purse of the average gardener. Therefore, from the commercial aspect of a National Show, buyers beyond those who buy already will be scarce, except of the old and cheap kinds. Take at random two flowers named by the rhapsodist on page 9, January 7—*Cædmon* and *Horace*. These were raised by me, one a full score of years, the other many years ago but have hardly yet entered the average garden. And there are flosses, real enough, to be set off against the visionary profits. There has been one quiet, delightful show, in the Edghaston gardens. There was, years ago,

a proposal to "popularise" it by its removal to (I think) the Birmingham Town Hall. Some kind and peaceful deity averted this; but this, or this kind of thing, will infallibly be carried out by the new machinists. And I hear—I had almost written I smell—a brass band.—G. H. ENGLEHEART.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Tomatoes.—A sowing of seed should be made now to supplement the supply of fruit from the autumn sown batch. Germinate the seeds in a temperature of about 60° in well drained receptacles of sandy soil, and endeavour to produce strong sturdy plants by growing in a light position. The autumn sown plants, if well rooted in 5in. or 6in. pots, may be placed into 8in. for fruiting. Pot firmly, using good fibrous loam, with some wood ash, old mortar rubble and well decayed manure added in small quantities.

Onions.—Where arrangements can be made for an early sowing in gentle warmth the present time is suitable. Use a fine light soil for the growth of the young plants, and when they are about 3ins. or 4ins. high prick out into boxes several inches apart, again using a fine rooting medium. This method of culture is certainly a good one and should be followed if possible when well grown bulbs are in request for any purpose. It is most noticeable, too, how particularly free Onions so started are from the maggot trouble.

Peas.—To obtain early pickings of this greatly appreciated vegetable, culture under glass in some manner must be resorted to. Plants may be grown in pots, boxes, narrow borders or frames, whichever may be most conveniently arranged for. A sowing should also be made in boxes and grown sturdily under cool conditions, to be available for planting outside on a warm border at the first favourable opportunity, when the weather and the soil are suitable.

The Hardy Fruit Garden.

Bush Fruits.—Where the wood of Black Currants was thinned out after fruiting was finished, little will need to be done now. If not done at the time mentioned, thin out the old wood, leaving sufficient of the strongest young shoots to preserve well balanced trees. With Red and White Currants pruning is done on the spur system, but for young trees being built up allow the main shoots to remain at about a third of their length, unless the condition of the wood does not merit it. Gooseberry bushes, too, are closely pruned by the majority of growers, while others allow a somewhat greater freedom of growth. In the one case it is only reasonable to expect finer berries, and in the other a greater amount, so the requirements of each particular garden may decide which method is to be followed. Whichever plan is adopted, the centre of all bushes should be kept open for this is beneficial to the trees and to those who have to pick the fruit.

The Flower Garden.

Supporting Trees.—Particular attention should be given in their young stage to specimens to ensure, if possible, straight growth, and also as a safeguard against injury in wind storms. Young standard trees in exposed grounds are best held in position by the tripod stake arrangement, but should a single pole be deemed sufficient it should be driven in on the side of the tree from which the wind is strongest and most prevalent. It is essential that the supports are not allowed to rub the trees, or perhaps irreparable damage may be done in a short while, therefore see that all ligatures are ample and well made. In the case of large specimens, where it may be necessary to loop several huge branches together, I think instead of chaining them together a more satisfactory result is obtained by using bolts for the purpose. Holes or cracks in trunks of prized specimens should be filled with cement, or a covering of sheet lead or tin adjusted, thus checking internal decay.

Fruits Under Glass.

The Orchard House.—The work of cleaning the house and the trees should be completed as soon as possible, so that a start may be made by closing it. The more natural the conditions can be kept

in this house the more satisfactory will be the results. Trees occupying permanent positions in the borders should, if necessary, be given a liberal top dressing of which nearly all should be good fibrous loam. It may be necessary in the case of old or exhausted permanent plants to supplement this top dressing with one of well decayed farm-yard manure, but in the majority of cases it is better to let the sun and air warm and sweeten the border before applying it. If any of the trees, whether planted out or growing in tubs, etc., are at all dry, give a thorough watering so that the roots will be in a suitable condition to respond to gentle forcing. Artificial heat must be sparingly used.

H. TURNER.

(Gardener to the Duke of Northumberland)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

French Beans.—Owing to its adaptable qualities for forcing, this delectable vegetable is largely grown during the early months of the year. Pots 8 ins. in diameter or boxes of a convenient size suit nicely. When sowing, avoid overcrowding, five plants to each pot being ample. Use a compost of light loam and leaf mould, allowing for free drainage. Red Spider must be guarded against, as the plants are readily susceptible to attacks of this pest when grown under glass, more especially when the atmosphere is allowed to become over-hot and dry. Use tepid water when spraying or watering the young plants. They enjoy a temperature at this time of from 60° to 65°. We find Canadian Wonder and Sutton's Superlative two of the most reliable varieties for early work.

Tomatoes.—Seed of an approved free-setting variety should now be sown or early growth. And as only a limited number are generally grown for this crop, a small sowing should suffice. Sow in a light compost, placing a piece of glass over the seed pan till germination takes place. Take care that the seedlings are not subjected to draughts or sprayed with water of too low a temperature. Sutton's Earliest of All is a reliable sort for sowing now, the fruits are of medium size and of fine flavour.

Cauliflowers.—A sowing of Early London should be made in boxes to provide a succession or to supplement batches that have been wintered in frames. Immediately the seedlings appear, place the box on a shelf near the glass and guard against damping.

Fruit Under Glass.

The Early Vinery.—Early Vines may now be started into growth, but little fire-heat should be allowed for the first two or three weeks. Keep a regular temperature, gradually increasing it as the buds break. Guard against high temperatures, as the consequences are generally weak wood and foliage that are unable to ward off the attacks of the various insect pests with which we are all more or less familiar.

Peaches.—Discretion must be used when ventilating and syringing the early house, more especially now that artificial heat is being admitted more freely. Should the weather prove dull, the damping of the paths will suffice. When the sun-heat causes the temperature to rise to about 65° air should be admitted, but the house must be closed down immediately any fall of the mercury takes place.

The Flower Garden.

Antirrhinums.—Seed of these delightful plants should be sown now so that strong, well grown plants may be had for planting out early in May. Sow thinly in boxes of light porous soil and place them in a genial, but not too high temperature. Keep the boxes covered with glass until germination takes place, when the covering may be gradually removed. Extreme care must be taken when watering as the seedlings damp off readily should there be excess of moisture.

Pentstemons may be sown and treated in like manner to that advised for Antirrhinums. Grown from seed in this way Pentstemons make strong plants and give a bright display during late summer and autumn.

Border Carnations in Frames.—Where circumstances compel growers to winter their plants in frames they should be looked over occasionally and all diseased or withered foliage picked off. Do not allow the soil in the pots to become dry. Ventilate the frames freely at all times unless very severe weather prevails. Give the surface of the soil in the pots a light dusting of soot so that the ravages of slugs may be checked.

Herbaceous Phloxes.—Should the transplanting of these fine perennials be contemplated, the work may be carried through during the first favourable spell of fine weather. Comprising as they do a wide range of exquisite colours and varying in height from 2ft. to 6ft., they are of inestimable value for the autumn border. The plants thrive well in most garden soils that have been deeply dug and well manured, the exception being hot gravelly soils, as they are noticeably partial to a cool root run. Should additional varieties be thought of they might include Tapis Blanc, white; Mrs. Oliver, salmon pink; Selma, soft pink; G. A. Ströblheim, orange scarlet; Cœur de Lion, rose, and Antonin Mercie, rosy lilac.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Hippeastrums.—Introduce a batch of good strong bulbs into a house with a temperature of 55° to 60°, and if they can be given some bottom-heat it is an advantage at this time. For early work use bulbs that were repotted last year and are thus in good condition at the root. There being no root disturbance, they will start more quickly, and such plants always give a certain amount of foliage along with the flowers. The plants should first be given a thorough soaking of tepid water to moisten the dry ball of soil; then remove some of the surface soil and examine the crown of the bulbs for mealy bug, which is a great pest and difficult to eradicate if it once gains a footing in a batch of plants. When the plants are in flower they may be removed to a warm greenhouse or may be cut for decorative purposes. The top soil which was removed should be replaced by a light rich compost to which some fine bone-meal should be added. Plants that require repotting should be shaken out and thoroughly cleaned, removing all decayed roots as well as all decaying matter at the base of the bulb. Examine for mealy bug and repot into a compost of good medium loam to which a little well decayed leaf-soil and enough coarse sand should be added to render the whole porous. To every bushel of soil a 6in. potful of fine bone-meal should be added. Newly repotted plants should receive very little water at the root until they make fresh roots and some top growth. This is a safe rule to follow with all newly repotted bulbous plants. Hippeastrums are by no means such difficult plants to grow as many people imagine. Later on I hope to deal in detail with the cultivation from seedling up to their flowering stage.

Rhodochiton volubile is a very beautiful greenhouse flowering climber that can be flowered the first season from seed sown any time during this month. The thin, flat seeds should be very lightly covered, or else they are apt to decay; they germinate readily in a temperature of 55°. They should be potted on until they are in 8in. pots, in which they should flower with great profusion during the summer and autumn. They should be stood on the stages and trained up under the roof glass; they are self-supporting by means of the leaf petioles, either on wires or string. If they can be planted out in a greenhouse or conservatory, they make very fine specimens in their second year.

Grevillea robusta is a popular and graceful plant for conservatory and house decoration, and seed should be sown at this time. It is an easily grown plant, yet many cultivators fail to raise it successfully and one frequently hears complaints about bad seed, whereas the failure is generally due to sowing the seeds flat, when they are very apt to decay. The thin, flat seeds should be set on edge and pressed gently into the soil. By this means they generally germinate well. Apart from its decorative value, young plants make a splendid stock for grafting some of the choice and beautiful flowering Grevilleas on, as most of them are difficult and slow of increase by means of cuttings.

Cyclamen sown last autumn and which were pricked off and have stood in seed-pans or shallow boxes all the winter should now be ready for potting off into "thumbs," using a fine rich compost for them, to which should be added some old mortar rubble crushed fine. They should be stood on a shelf well up to the roof glass. They enjoy moist atmospheric conditions at all times, and at this stage of their cultivation should be given an intermediate temperature of 50° to 55°.

Solanum capsicastrum, with its profusion of orange scarlet fruits, is very popular for the autumn and winter decoration of conservatories.

Plants can be raised at this time either from seeds or cuttings, and if carefully attended to will make good plants by the autumn. The young plants should be brought on in a warm greenhouse, and later on may be transferred to cold frames. During the summer they should be stood on an ash bottom in the open, or they may be planted out for the summer, in which case they will require less attention as regards watering. Whatever method of cultivation is adopted, they should be pinched occasionally to induce a bushy habit of growth. They are somewhat subject to attacks of red spider, so should be kept well syringed, especially during spells of hot, dry weather.

Ardisia crenata is another greenhouse plant the seed of which should be sown at this time, or it may be propagated by means of cuttings. This plant bears a profusion of small dark red berries, which remain perfectly fresh on the plant for at least nine months. Unlike the *Solanum*, this plant is of slow growth, taking three years before it reaches a suitable size; thus, to keep a yearly succession a batch of plants should be raised every year. The seed is hard and takes a long time to germinate. This can be hastened, however, by soaking the seeds for twelve hours in warm water. During its growing period this plant should be given an intermediate temperature. When it has attained flowering and fruiting size it will stand in a cool greenhouse and make a good lasting subject for house decoration.

FORTHCOMING EVENTS.

January 26.—Gardeners' Royal Benevolent Institution, Annual Meeting and Election at Simpson's Restaurant, Strand, London.

January 31.—Royal Horticultural Society's Fortnightly Meeting.

January 31.—National Dahlia Society's Annual General Meeting at the Royal Horticultural Society's Hall at 3 p.m.

The International Bureau for Registration of Novelties.

The Chamber of Horticulture has been requested to announce that all preparations for the above are now complete, and that the Bureau is ready to commence registration. The following particulars have been supplied and should be noted: 1. That the International Bureau for Registration of Horticultural Novelties, founded by the Federation Horticole Professionnelle Internationale, will commence on January 1, 1922, with the object of protecting the raisers of new plants, as to (a) prior right of raising; (b) ownership of name chosen; (c) possibility of claiming both; and also (d) adequate advertisement to make the novelty known to the horticultural world. 2. That official forms necessary for declarations will be addressed to raisers on receipt of demand accompanied by the amount of the registration fee, which is 10fr., plus, if desired, the amount necessary to cover the cost of supplementary declarations, at the rate of 5fr. a line of forty letters, signs or intervals. 3. That official forms can only be obtained from the Bureau Agent, M. L. Sauvage, 6, Rue du Débarcadere, Paris 17. 4. That cheques and money orders be made payable to M. Sauvage. 5. That, on demand, raisers will receive, without charge, a small booklet containing the Rules of the Bureau and all particulars concerning the keeping of the various registers, confirming the rights of the declarers, and providing for the establishment of International legislation on this subject in due course. The Chamber will be pleased to issue further information on the above from time to time.

Answers to Correspondents

NAMES OF FRUIT.—W. R. J.—Aprles; 1, Manks Codlin; 2, Old Peasgood; 3, King of Tomkins County; 4, Roundway Magnum Bonum.—Hon. Mrs. Sandbach.—Apple Tower of Glamis.

NAME OF PLANT.—Quebec.—*Statice sinuata*. *Campánula Raddeana* is a perennial and listed by most hardy plantsmen. Seed could probably be obtained from Messrs. Thompson and Morgan, Ipswich.

Covent Garden, W.C.2.

Always at this season of the year, the Editor is being bombarded with enquiries relative to the seed-order which is to many amateurs one of the events of the gardening year. Even to the most blasé of professional gardeners there is a never-failing pleasure in perusing a good seed catalogue and selecting varieties not only for the actual order in hand but for trial some other time. Many of the sorts so marked never get ordered in reality, but the anticipatory pleasure is there just the same! Realising, then, the importance of this, the principal seed-order of the year, we have during the past six weeks given many suggestions as to what persons of varying temperament might well include in the seed list. The time for such hints is fast passing, however, as such seeds as those of Parsnip and Broad Bean should soon be in the ground—supposing, of course, that reliance is not here placed on autumn sowings. Bearing this fact in mind, it seems fitting that next week's issue should be largely devoted to further consideration of some of the many aspects of the seed-order.

The Proposed National Daffodil Society.—Time draws on, and very shortly the National Daffodil Society will either be a society in being or a memory of the might-have-been. While there have been expressed in our columns naturally divergent opinions as to ways and means—a healthy sign, since it betokens interest—only one voice has been lifted up in real opposition to the creation of an independent National Society. That voice is, it is true, the voice of one whose opinion must needs carry weight in the Daffodil-lover's world. Still, the opinion of one, however eminent, cannot weigh down the matured judgments of so many, especially when among the great majority may, as here, be numbered some also deservedly esteemed by those interested in Wales' national flower.

A Vast Difference.—It is incumbent upon everyone, whatever his walk in life, always to visualise to the utmost of his power the position and standpoint of those whose views fail to coincide with his own. Should he bring to the question at issue all his

ability and judgment and, unbiassed by preconceived opinions, re-weigh things fairly, it will sometimes happen that he finds his own original view-point a mistaken one. It has been well said that the man who never changes his mind has no mind to change! Even where investigation but confirms one's opinion, one's opponent must have indeed a poor case if he can illuminate no dark corners with his arguments. In his letter in last week's issue the Rev. G. H. Engleheart recapitulates Mr. Jacob's summary of the essential duties of the new society with what he describes as "very obvious comments." Very obvious they are, indeed, and, like most obvious comments, fallacious, for here there is a confusion of thought. Mr. Jacob summarised the duties which the society would have to undertake. Mr. Engleheart assumes that the undertaking of these duties is the society's *raison d'être*. Such is not in fact the case. Were there an efficient Metropolitan Society which did for the Narcissus in London what the Midland Society does in its own territory, there would not now be an agitation—the promoters will not quarrel with Mr. Engleheart's word—to form a National Society. It is because many lovers of the Daffodil feel that the London exhibitions of their favourite flower should no longer be dependent upon what they consider the lukewarm interest of the Royal

Horticultural Society that they are agitating for a National Society. It is not the yearly programme which needs radical alteration, but the way in which that programme is carried out.

Rumination!—These things notwithstanding, the supporters of the new society will do well to ponder Mr. Engleheart's reference to the comparative popularity of the Daffodil and the Sweet Pea and the reasons therefor. They would do well to chew upon this—that if the Daffodil shows are to be popularised, the difficulty raised must be overcome. Popularity can only come with popular attractions. It is true that the newest varieties can make but a limited appeal, their price being too heavy for the light purses so prevalent to-day. Comparatively few amateurs, however, purchase the newest Roses, yet the Rose shows are always a success, and the novelties are always difficult to see because of the press of people who like to see what progress is being made. It may be said that many of them are selecting Roses for purchase a year or two hence. It seems improbable! Before that time comes much more information will be available as to their behaviour and ease of cultivation. It is the so-called decorative classes which have made the Rose a popular exhibition flower, and it will be decorative classes that, given the opportunity, will do the same

PLANTERS SHOULD NOT OVERLOOK THAT BEAUTIFUL BRAMBLE, RUBUS DELICIOSUS.

for the Daffodil. The trade, after all, still sell bulbs of the older varieties. Why not exhibit these varieties decoratively in order to make a definite appeal to the "man in the street"? Why could not there be a class for bulbs arranged in turf—moss might be utilised to represent the turf at the discretion of the exhibitor—as naturally as possible, varieties only being employed which are moderate in price and which succeed under turf? Again, could not there be a class for them arranged on rock-work, with, of course, a suitable interplanting of rock plants? Floral designs and table decorations are more obvious ideas. Such exhibits would do wonders towards popularising the shows and, because appetite grows by what it feeds on, would do much to foster interest in the purely florists' varieties Daffodil enthusiasts love so well.

TWO NORFOLK GARDENS

The altered conditions which have prevailed since the war have adversely affected the upkeep of many stately and spacious gardens. Below is given a brief description of two such still in good order.

A FEW notes on Norfolk gardens may be of interest, as nothing has, to my knowledge, been written of them lately for THE GARDEN. These gardens all belong to the older family estates, now so rapidly passing either to new owners or to the builder. I will first deal with Blickling Hall, where the estate is still entire. It belongs to the Marquess of Lothian, but is now let to an American.

It is, considering the shortness of labour, wonderfully kept up. Indeed, one would hardly believe it possible to keep grass edges and walks so neat and the gravel paths so clean, to say nothing of those other details in a garden which usually point first to want of labour.

This beautiful Tudor mansion, a few miles from Aylsham, lies in well wooded country. It was the home of Anne Boleyn. Mr. Oclée, who has been head gardener there for over fifty years, was good enough to show me round. There is but a moderate amount of glass. The wall fruit, however, is in splendid condition and really excellent crops are obtained. The moat round the Hall has been filled in and turfed. The herbaceous garden is very good; indeed, the flower gardens generally are admitted to be the best in Norfolk. They were greatly admired by Queen Alexandra on an occasion when she paid a surprise visit.

A remarkable feature at Blickling is a Plane tree (*Platanus occidentalis*) on the lawn, the branches of which give the effect of having layered themselves; it is of natural growth, and the branches extend 23yds. from tip to trunk. In spring the ground beneath this tree is covered with Primroses, both wild and coloured. The tree, which is of no great height, is of unknown age.

Azaleas do splendidly, despite the bleakness of the climate. The soil is, however, on the light side and naturally warm. A large bed of

Azaleas, exposed to all the north wind that blows, never suffers; in fact, in no part of the grounds has there been loss of them from exposure to cold winds and frost. Lilies do not flourish, though at Westwick, not many miles away, they do well. A few bulbs of *Habranthus pratensis*, planted at the bottom of a south wall, have now

BLICKLING HALL. THE DRY MOAT.

quite filled the available space, though no special care was taken with them. This seems, none the less, a difficult plant to establish in some places.

The park, with its herd of deer, is magnificent; no brand-new grounds can show the stately beauty or produce the atmosphere of peace and harmony which cling to these century-old estates.

The last Lady Lothian, who was a widow for thirty years, devoted her widowhood to Blickling and its people. She was much beloved.

At Gunton Park the surrounding land has been sold, but the house and park are still owned by Lord Suffield, who resides there entirely.

Here one is nearer the coast, Cromer being only seven miles or so away. The drive through the park was, at the time of my visit, perfect with glorious autumn tints. A clearance of shrubbery near the house has here been effected to open up a view of the lake, which is a fine stretch of water. The wood on its further slopes has, near the lake, been planted for colour effect, and the planting could hardly have been improved.

The rose garden at Gunton Park is one of the best planned I have seen. One wing of the house was destroyed by fire; only the outer walls now remain. Gunton is noted chiefly for its fruit, and in the large, well appointed fruit room I saw many varieties of Apples and Pears, all well grown.

At Gunton, as at Blickling and a few other places, I was amazed at the order shown. These large old gardens were planned in a day when labour was cheap; but one can tell with certainty the places where the head is not only a good gardener, but a particularly able organiser, with the consequent effect on the staff. One cannot but think that employers do not sufficiently realise this. I have seen at least one place (not in Norfolk) with twice the staff that Blickling had, where the condition of the wall fruit trees was appalling, and there seemed but little order or neatness anywhere. The war was, it is to be feared, a great excuse for many incompetents.

B. G.

THE SPRING O' THE YEAR

I BELIEVE that, officially, spring begins on Equinox day, March 21, when the sun enters Aries, and for my part I have no wish to dispute the official view of the seasons. Though I should have thought, had astronomy been allowed to decide the point, that the dead or winter season ought to extend to an equal distance (of six weeks) on the further and on the hither side of the winter solstice, or shortest day, December 21—that is to say that if the seasons are held to depend on the various positions of the sun in its orbit, winter ought to begin about November 7 and end about January 31, in which case our first spring day would be February 1. However, I have no wish to argue this, as if it were a matter in dispute, since there is little profit in disputing what is official. But clearly there are various springs. There is, as I have said, the official or purely bureaucratic spring, and there is the cosmogonic or solar spring; but there is also the psychic spring that one "feels in one's bones," which, for myself personally, as for other creatures of instinct, like thrushes and Crows, is really the only spring that matters. Unfortunately, the spring of one's bones is indeterminate as to the dates of its beginning and ending. You feel it, which of course is final, since no wise person would attempt to reason with feeling. But you do not feel it on the same date every year. Speaking for myself, and for no one else, of course, my own soul and bones usually respond to vernal influences on or about

February 1, such response thus squaring, curiously enough, with the cosmic indications of such heavenly bodies and constellations as the sun and the signs of the Zodiac.

Now, as it happened, those various spontaneous stirrings and impulses which concur to make this "spring feeling" converged this year, not on February 1, as might have been expected, but on the ridiculously early date of January 9. Not that the 9th was by any means an ideal day as regards weather. There was little sunshine; indeed, I cannot remember that there was any. The sky was grey, and the air was moist and "muggy." The wind was brisk, at times even boisterous, but (and here lies the crucial fact that explains so much) it was a west wind. A west wind, you will observe, which of all the winds is the most bland, as the east is the most pernicious. The "breath of autumn's being" this wind is styled by Shelley, who pictures it, if I rightly remember, as piping a funeral pibroch to the dead leaves, "yellow and black and pale and hectic red." But poets, as we know, have too often the disingenuous habit of twisting the facts of Nature to the purpose of the moment. Not that I wish to quarrel with the disingenuousness of poets—it is part of their stock in trade. A poet gives either half a truth or a truth and a half, and if he stated just the truth, neither more nor less, would be esteemed but a poor stick. The west wind may be the breath of autumn's being. I do not say that it is not. I dare say it is. But it is the very life-blood that flows through the veins (or, to be quite exact, through the arteries) of spring, of which vital fact Shelley says nothing—a clear instance of *suppressio veri*. Now on January 9 the west wind was flowing through the system of Nature in a full and brimming tide, of which there were various sufficiently convincing signs, though for my part I required nothing more convincing than the sight of neighbour Snow's superannated hack, Jenny, careering in the church meadow and kicking up her heels in a fine frenzy. "Jenny knows," thought I, "Jenny feels it," and, but for certain physical disabilities, I would have kicked up my own in sympathy. It was, in short, a resurrection trump, that blast of the west wind, stirring the living juices in dead flowers and birds long silent. Flowers? I have been gathering *Iris stylosa* and Christmas Roses all the winter, but, though they certainly made the winter more bearable, it never occurred to me that winter was any the less surely winter because they were there.

It was, however, another guess matter when, on the morning of the 9th, a Crocus (purple-striped and fawn outside, veined mauve within—*Crocus Imperati*, I believe) emerged as through a trapdoor on the gravel walk. That was surely spring and nothing else. There was also a Snow-drop or two of the *Elwesii* breed; but Snowdrops are an excitable and uncertain race that may appear at Christmas, long before the west wind has given the signal. Again, there are the birds. Why should a thrush select January 9th to perch on my old Blenheim Orange and deafen the neighbourhood with his din until it was too dark to sing?

Had it been a robin that warbled his little ditty I would have associated the sound with the winter season as readily as I would an icicle. But though occasional thrush notes may be heard in suitable winter weather, a daylong, gala performance from the top of a Blenheim Orange is a different matter, and requires an explanation of its own. Other notes heard on the 9th, though not normally due till February, were the "fink, fink" of the chaffinch and the warble of the hedgeparrot.

SOMERS.

COMMENCING A ROCK GARDEN

THE rock-loving plants that yield the greatest measure of success with amateurs are notably sunlovers, and it is to this section that the beginner can turn with every confidence, their main characteristics being that they are perfectly reliable, generous in flowering, unquestionably hardy and not costly to procure. In small gardens, and with the plants I am going to name, there is

I have come across. *Erysimum pulchellum* is a pretty, flat evergreen with flowers of gold, very freely produced during April and May. *Cheiranthus Allionii* should be placed close to the last named, as the striking orange of its flowers shows to distinct advantage against the gold of *Erysimum*.

Phloxes, like *amoena* and reptans for early flowering, and the forms of *subulata* for a later

display, give a wide range of colours from white to deep rose, while there are several with flowers of a delicate lavender shade, such as *G. F. Wilson* (*lilacina*).

Androsace sarmentosa is one of the best and certainly the easiest to grow of this beautiful group; it throws out delicate runners like a Strawberry plant, and if these are pegged down and nice gritty soil placed under the little plants they soon root and take up an independent existence.

Dianthus is a genus to conjure with; try a good strain of seed of *D. plumarius* and plant the seedlings in dry-wall, rock garden or sharp-pitched slope and the feast of colour will be a revelation. Among the species that I recommend for a maiden effort are *cæsius*, *deltoides* or *graniticus*, *neglectus*, *alpinus*, *arenarius* and *microlepis*.

Campanulas are important and should include *G. F. Wilson*, *pusilla*, in three colours, and *muralis* for early summer, and *Profusion*, *haylodgensis* and varieties of *carpatica* to flower later.

Gypsophila repens (white or pink) and *Saponaria ocyroides* (rose) with its variety *splendens* (crimson) are glorious plants to drape over the face of a rock, and the flowers are massed in

A PLEASING ROCK GARDEN PICTURE, THE IDEA OF WHICH COULD BE INTRODUCED IN QUITE A SMALL GARDEN.

never the same urgency to employ each kind in masses, although a few of the most effective should always be given this prominence; the majority, however, in time swell out and form a mass in themselves.

No rock garden should overlook the merits of *Arabis alba* fl.-pl., *Aubrietias*, all varieties, and *Alyssum saxatile* and its variety *citrinum* and also the double form, their only drawback being that they are too common and, if I may say so, too easy to grow. Nevertheless, they are the glory of the rock garden and dry-wall in spring, and their perennial and prodigal wealth of Hossain will always command admiration and win for them a place of honour in our gardens.

The perennial Candytufts (*Iberis*) become perfect snowdrifts when in flower; Little Gem, Snowflake and *correaifolia* are three of the best

such a way as almost hides the foliage from view.

Several of the *Hypericums*, with their Rose of Sharon flowers, are among the best of rock plants. *Coris* forms neat, erect, heath-like bushes, whereas *repens* and *reptans* are prostrate in growth; the flowers in each instance are yellow and the centres are quite filled up with the elegant filaments of the anthers.

I am of opinion that every rock gardener should attempt to grow *Lithospermum prostratum* and its variety *Heavenly Blue*. At first effort you may possibly fail; nevertheless try again, and ultimately succeed, for the Gromwell (*Lithospermum*) blue is in this instance faultless. Plant them very firmly indeed, for they are really hard-wooded shrubs, although so dwarf, and if the natural soil be limestone or chalk, remove it and replace with soil free from lime.

PLANTS IN THE MORAINE.

Running water at the depth of a foot or so is essential to a true moraine, but many Alpines flourish in a compost largely consisting of stone even without this advantage.

Lychnis Viscaria splendens and *Oenothera riparia* are useful and effective plants; the flower stems are borne erect, and this is of some value when placed among flat-growing plants. Many of the silver *Saxifragas* are useful in the same direction; those I specially mention for beginners are *Aizoon rosea*, *A. notata* and *A. La Graveana*,

Cotyledon pyramidalis, *Hostii*, *lingulata lantoscana* and *Macnabiana*.

Tunica Saxifraga and *Silene alpestris* are very dainty for a crevice between stones; and *Thymus Serpyllum* (especially the varieties *coccinea* and *alba*) and *T. lanuginosa* are charming for their scent and flowers. T. SMITH.

GARDEN ECONOMIES

Plant Dwarf Peas

Not everyone will agree with the writer's sweeping condemnation of the taller Peas. In wet summers, especially, they prove their worth, but there is, none the less, much truth in the arguments brought forward.

IT behoves any garden owner and employer of highly paid labour to do the very utmost to ensure two objects—to lessen the cost of production and to increase the output. In gardening there are many details that can be thus treated; not the least important among them is the production of green Peas.

The Dwarf Pea has been brought to such perfection that the yield in size of pod and Pea is equal to that of almost any of the tall varieties, with one possible exception in the show bench Pea. Dwarf Peas can be produced at little more than half the cost of the tall varieties. In fact, yield for yield, with dwarf or tall Peas over the same area of land, the comparison is in favour of the "dwarfs."

Let us see how it is done. Tall garden Peas need planting from 4ft. to 6ft. apart in the rows, require sticks from 4ft. to 6ft. high, entail the expense of purchasing the sticks and the labour of sticking the rows, both expensive and unnecessary.

Dwarf Peas need only from 18ins. to 24ins. between the rows, and after planting and hoeing, need no labour at all until the crop is gathered, no sticks, no labour in sticking, and later in

removing the fence-like hedge of sticks for storage. Let any garden lover try them. Compare six rows of Dwarf Peas of 12ins. to 18ins. in height against two rows of tall Peas of 5ft. to 6ft. and I am sure the result will astonish him, while for table use and for market the Dwarf Pea yields no points to its tall brother.

There are two or three varieties, among a host of other good sorts offered by seedsmen, that are particularly useful—good sturdy growers, magnificent croppers and splendid cookers. They are Peter Pan (18ins.) and Sutton's Little Marvel (15ins.), both Marrowfat Peas, big of pod, big of pea, colour and flavour unexcelled. Then we have that wonderful Pea Witham Wonder, and it is a wonder! The plant itself is not so robust as the two previously mentioned varieties or the pod quite so large, but the yield and quality more than make up for these deficiencies. The plants are loaded with medium-sized fat pods that simply burst with the contents packed closely together, while the pods themselves are thin in texture, so that the yield in shelled Peas is very much greater than from many tall varieties with big fleshy, half-empty pods, however big the individual Peas in the pod may be.

Dwarf Peas can be grown in succession equally as well as the taller kinds; in fact, here again the economy in production is in their favour. A few rows planted at intervals of about a fortnight from March to June, and in most soils even in July, will give a continuous supply all the summer months, with no care or thought as to expense of sticks or labour of sticking, and they need much less water.

Let me give the intending planter of Dwarf Peas one or two tips for the production of the best results, although these tips apply equally well to all and any kind of Pea, even to Sweet Peas grown for bloom or seed.

Make your trenches not more than 2ins. deep, the width of a narrow draw hoe. If possible, leave them open to the air and sunshine for twenty-four to forty-eight hours; it is not absolutely essential, but helps the future crops. Do not dig in a lot of manure of any kind, Peas do not need it on good garden soil. Instead mix basic slag of good quality (28 to 30 per cent.) with twice its bulk of ashes from a rubbish fire and dust this mixture down the open rows, a good handful to the yard run of rows. Plant the Peas singly in the rows 2ins. from Pea to Pea in any direction—half a pint of Peas will plant 20yds. of row. Never plant too thickly, rather err the other way. Put your Pea seed into a tin, add half a teaspoonful of red lead in powder and a teaspoonful of common paraffin and shake well—plant and cover immediately.

When the Peas come through the surface, if birds or other destructive influence be at work, spray the rows with lime-sulphur fluid from an ordinary spraying machine as used for fruit trees, using a strength of one part lime-sulphur fluid to eighteen to twenty parts of water. This dressing is not only protective to ward off the attacks of birds and insects, but is beneficial to the plant itself as destroying all germs of mildew. Hoe the rows, not up and down the row as is usually done, but across the rows, drawing the soil towards the plants and not away from them. Nothing more is needed until the crop is gathered, no purchase of expensive sticks, no heavy labour charges in sticking, no treading down the soil between the rows in the process of sticking, no waste of time in clearing and storing the sticks after the crop is over.

The rows of Dwarf Peas can be pulled off quite easily after the crop, the land hoed over, and it is ready for the crop of winter Broccoli, Kale, Savoy, Cabbage or what not; for the Brassica tribe always do well after Peas owing to the habit of the Pea to store nitrogen in the soil round its roots.

Try Dwarf Peas and you will never waste money on Pea-sticks again, but do not forget to plant the seed thickly. S. WARNER HAGEN.

On Making the Greenhouse Profitable

Peach and Nectarine Trees in Pots.

FOR those owners of gardens whose glass-house accommodation is limited and who wish to have a few choice Peaches and Nectarines the cultivation of the trees in pots is to be recommended. The chief advantage of this form of culture is that the trees can be placed outdoors when the fruits have been gathered and the house utilised for growing *Chrysanthemums* and other plants during the winter months.

The Importance of Harmony in Planting

The writer appeals for the more effective massing of suitable plants rather than the heterogeneous medley too often seen.

Where ripe fruits are desired in June, the trees should be placed in the house at once, but no fire-heat should be applied for the first fortnight. If the temperature of the house should reach 55° by solar heat, the top ventilators must be opened a little at midday, closing them early and at the same time damping the walls and paths.

When the trees have been indoors a fortnight, a night temperature of 50° should be maintained, allowing for a rise of 5° during the day. During the flowering period a drier atmosphere with a free circulation of air is necessary for obtaining a good set of fruits. The flowers must be carefully pollinated with a rabbit's tail to ensure fertilisation.

As soon as the fruits have set, disbudding of the young shoots must be attended to, taking care not to leave them too thick in the centre of the trees; at a later stage these shoots will require stopping. Shoots starting from the base of the fruit-bearing wood should be encouraged and may be pinched at the eighth pair of leaves and other shoots at the fourth pair of leaves, always taking the points out of the stronger growing shoots first.

As soon as the fruits are as large as marbles, they should be thinned. The temperature from now until the stoning period is over should be 55° at night and 60° by day, with a little top ventilation whenever the weather is favourable.

When stoning is completed, which will be about twelve weeks from housing the trees, the fruits should receive their final thinning. Young trees in pots 10ins. to 12ins. in diameter will carry twelve to eighteen fruits; older trees in pots 18ins. in diameter will carry three to four dozen good fruits. The trees will now benefit from a light top-dressing of equal parts good loam and horse droppings, adding an 8in. pot of bonemeal to each barrow-load of compost.

Cultural details from now until the fruits commence ripening consist of giving the trees ample supplies of water at the root and frequent applications of diluted liquid cow-manure with a light sprinkling of Le Fruitier on the soil once a week. The trees should be forcibly syringed twice daily, finishing in the early afternoon to allow the foliage to dry before night. Should aphids or red spider attack the trees, the house should be lightly fumigated.

When the fruits commence ripening syringing must cease and the ventilators (both top and bottom) remain open by night and day, as the admission of fresh air improves both the colour and the flavour of the fruits.

After the fruits are gathered the trees must not be neglected, but kept well watered and fed to ripen up the wood for producing the following season's crop.

About the middle of September the trees should either be repotted or top-dressed, using a compost of five parts loam, one part lime rubble and wood ashes, with a sprinkling of bone-meal.

After potting, place the trees in their winter quarters, where they can either be plunged to their rims in ashes or covered with bracken to prevent the pots being damaged by frost.

Reliable varieties of Peaches are Stirling Castle, Dymond, Peregrine, Royal George, Kestrel, Crimson Galande. Nectarines: Cardinal, Early Rivers, Elruge, Pine Apple and Humboldt. Trees treated as I have recommended will continue to give good returns for a number of years. Some in my charge are nearly twenty years old and annually produce good crops of fine fruit. Apple, Pear, Plum and Cherry trees may be grown in a similar manner, although somewhat cooler treatment is better for them, and the end of February is early enough for housing the trees. C. H. W.

AN article in THE GARDEN of January 14 emphasises the importance of contrast in the planting of trees and shrubs. I should like to add that "harmony" in such planting is even more important and much less commonly achieved. I feel sure the writer of the article would agree that the "mixed shrubbery" is, in at least eight cases out of ten, dull and without character, and that this is due not to lack of diversity but to the excess of it. There are too many "contrasts," not too few, so that the total effect of the mixture is merely monotonous.

I have in mind a large garden mostly consisting of shrubbery where all the old dodges, such as the backing of Acer Negundo with Purple Beech or Plum, and the introduction of upright conifers among shrubs of contrasting habit, had been employed *ad nauseam*. The result was not stimulating, it was simply dull. There was space enough to have planted a whole grove of snowy Mespilus, a secret garden of Persian Lilac, a valleyfull of Rosa polyantha Thunbergi or Berberis vulgaris. Those would be features one would remember when one came away; of the mixture one remembers hardly anything.

The trouble is due partly, I think, to insensitiveness to what is incongruous, partly to the desire to get in as many different sorts as possible. Examples of insensitiveness—not to say blindness—can be seen in most of the gardens beside the roads around London. Everywhere Prunus Pissardi can be found being made to do its dreary old trick of supplying contrast, usually to Acer Negundo, Laburnum and pink May. (It is a

solitary exotic-looking clump of Bamboo. Or, worst of all, mixed up with the exquisite yellow-green of young Beech leaves one finds some incongruous Spruce or a blue Cedar.

In the article I have referred to, dwarf Junipers are recommended as "particularly useful for the contrast they afford to shrubs of more usual habit." I cannot help thinking, however, that it would be a mistaken use of this advice if the reader were to associate Junipers with most of the commoner flowering shrubs, such as Philadelphuses, Deutzias, Weigelas and the like. On a half-wild bank or in a rocky or moorland place, or in suitable woodland, Junipers can look congruous and delightful, especially as a foil to the shadowed greyish rose of Heaths such as Erica darleyensis. But as a contrast to most shrubs they would generally look out of place.

The desire to get in as many sorts as possible into a limited space is, of course, inevitable for every gardener; but unless the desire is kept severely in order it will ruin the appearance of every garden, save from a botanical point of view. Restraint, economy of means, is just as essential in garden planting as in painting or in cookery. As a painter I find that when I see a planting of shrubs I generally want to sort out the ingredients and to simplify, always to simplify. Even the illustration to the article I have quoted, "A well arranged shrubbery border," seems not broad enough in treatment. It is unwise to generalise on such a subject, but perhaps one may safely say that as a general rule the grouping of similar shrubs should predominate over the groupings of dissimilar ones. If one spends one's care on

EFFECTIVE HERBACEOUS PLANTING. BOLDLY CONCEIVED AND HARMONIOUSLY ARRANGED.

most difficult plant to use well, but can be invaluable if kept rather apart with suitable company, such as Bocconia or Clematis montana rubens and the purple-leaved Weigela rosea, or with grey-blue flowers such as Echinops and Eryngium.) Golden Elder and other so-called golden shrubs are used with dreadful frequency for giving contrast. In the company of homely old friends such as Hawthorn and Ribes one comes across a

bringing together those shrubs which have grey leaves of congruous form and colour, one is much more likely to achieve a beautiful result than if one sets out deliberately to oppose a grey leaf to a bright green one. Santolina and Olearia stelulata, Rosa rubrifolia and Sea Buckthorn, Lavender and Perowskia—if one begins with a few simple associations of similar colours such as these, one has a foundation on to which the more

exciting colours can be added with full effect. (Red Valerian, for instance, would warm up the Olearias, Tiger Lilies and Clematis Flammula would help the Buckthorns.) If the whole framework of a piece of shrubbery consists of Sweet Bay, Arbutus and Laurustinus, the elements that may be added—*Kerria japonica* fl. pl., or *Philadelphus Norma*, or whatever they may be—will stand a much better chance of making a memorable effect than if they had had to

compete with the miscellaneous "contrasts" of a mixed shrubbery.

It would be a dull garden that had no contrasts—where nothing so bright as an orange Lily was ever allowed near a pure blue Delphinium, where all the colours were kept muted like the pink of *Dictamnus*, and where everything grew exactly according to a plan. But the search for contrasts can easily be overdone, with a result that is not stimulating but monotonous. A PAINTER.

come to us new and pure with each passing day. Emblems they still remain, of every charm the world contains, and the fairest of all its products. Throughout all poetry, romance or mythology there exists no standard of beauty higher than that of flowers and no symbol that has been so frequently employed throughout the ages. And so after the day of strife the garden becomes our rest and entertainment—"Not in the busy world, nor quite beyond it"

Again, the immutable years move on, and the impulses, ambitions and dreams of youth are gone, and their place is taken by the memories, regrets and reminiscences of the days that are no more. Friends we have known, some dear to us, some that, like ships at sea, speak and pass on their way, and some that were intimate parts of our lives and ourselves. Still, to us the garden shall remain a harbour of refuge—its "smooth alleys for aged feet," its sunny, sheltered resting places when the spring or autumn air is cool, and the deepening shadows in its leafy shades, or as the summer sun sinks low, shall have each their turn in our desires. More than ever, then, it will become our garden of memories. Each subtle fragrance diffused on the still evening air will have its power over our senses and transport us back along the river of time to the days of long ago. Nothing is so potent to recall the episodes of the past as the odours of a garden, and though you walk in the busiest mart of the busiest city of the world the breath of Lily of the Valley, Violet or Wild Rose will call up before your eyes a panorama of events in which you played your part. And is not the cry of humanity: "From battle and murder and sudden death deliver us," so that when our feet can no longer falter along the well-worn paths, and we leave for ever the bowers and pleasaunces, we may find our rest at last in God's Acre of garden.

Is there, then, anything absurd in the plea for a garden of memories? A garden wherein each plant or tree or shrub shall be a record of some event, either in our own lives or in the lives of our friends. In it many, many things we love for their own sakes would have a place. There would, of course, be Rosemary for remembrance of one who went forth to fight the battles of the world, and of whom nothing is left to us but—a memory. Forget-me-not for those whom duty called to the uttermost ends of the earth and who throughout the long years have left with us nothing but a memory of all they were to us. Traveller's Joy would indicate the visit of one who came, and for a brief space filled our lives with his presence and went on his way. Purging Thorn would record the time when we had fallen short in the call of friendship, and one we wished to keep within our own circle had ceased to be, and we knew it was because we had not come up to the exalted standard of hospitality or friendship demanded. Heart's Ease for the day when we laid to rest that tiny fragment of humanity whom we knew as Goldilocks. Passion Flower would record the great event in the life of our youth. Jasmine would be there because it was while its odour filled the midnight air we leaned from our window and thought of the triumph of the day that had gone. Musk, because its perfume would remind us of that evening when something happened that turned the course of our life. Flower-of-an-hour would take us back to the day when all our hopes and ambitions were concentrated on a single cast of fortune, and it failed us, and the world went dark for a space. Then there would be the plants that had been given us by friends because they loved them. We should ask of all we knew, his, or her, favourite flower, and plant it in memory. Many others there would be, and all would be there because—well, just "because." A garden o

A GARDEN OF MEMORIES

All our gardens are, to a greater or lesser extent, gardens of memories, though not deliberately planted as such.

MEMORIES of the years that have gone, of the friends we made and loved and lost, of the joyous years of our youth, of the struggles, hopes, fears, even the joy of battle in later life, but more than all, the memories of the calm between the storms, of the rest that comes after the turmoil and strife in the world that lies beyond the green confines of our garden! A garden of memory: The term sounds like some poetic flight of fancy. And yet, even in this materialistic age, when the suppression of emotion is credited unto us as the evidence of strength, and sentimental expressions of regard for the things that were a betrayal of our weakness, is there not something musical in the very words? There is an infinite tenderness in such a conception that appeals to the chords within us that vibrate to all the joys, fears, hopes and sorrows of life.

Indeed, is not every garden that we have ever known a garden of memory? The epic of life is written in the gardens of our lives. Who is there among garden lovers that can forget their first garden? As children, with tottering feet, led by careful protecting hands along the smooth flower-decked walks, and though our steps were uncertain and our language limited and lisping, we searched with eyes alight for some new jewel of colour. We worshipped colour in those days, and it is a primeval instinct that we have never lost. We were not shown the garden in the days of long ago, for it was we who conducted the little procession of our admirers, and made them pause by our imperial gestures, and baby lisping, as we called attention to the things that attracted us. The newest and rarest flower in the garden had no attraction for us, but in the crimson glow of a big red Pæony we found something we could understand sufficiently to wonder at. This is the real joy of the garden, to wonder at what we see therein:

"Flower in a crannied wall,

I pluck you out of the crannies,
I hold you here root and all, in my hand,
Little flower—but if I could understand
What you are, root and all, and all in all,
I should know what God and man is."

But first it was the colour instinct that attracted us, and all through the years it has been with us—the sensuous delight in colour that has been our greatest incentive to gardening.

A few years later, the garden became our playground. And what a fairyland it was. Every purple-shadowed Nook, and every dim recess in the adjoining woodland where "the garden meets the wild," was a giant's cave or an ogre's castle, which, as the evening shadows deepened, our imaginations peopled with impossible monsters. Sometimes we, fearing, yet timidly braved the unknown and ventured our steps within the dismal precincts. Who knows what awe-inspiring

creatures we did not expect to find there? Perchance it was there that we learnt the elements of that courage that should stand us in good stead in the greater, but not more real, adventures of after life.

The flowers were fairies to us in those days, fairies to whom we talked and who talked to us in a language we understood quite well, but have since forgotten. The glowing petals were but the royal habiliments of our queens and princesses, and the dewdrops but their jewels. The stately Lilies were the queens; a multicoloured host of courtiers in the form of Roses attended them, while all around a noble army of blue guards in the form of Larkspurs protected their royal presence.

Again the years rolled on, and we carried every image from the schoolroom into the garden. Those stories of the departed great had but an indefinite meaning to us within four walls. Here we found something tangible to which we could attach their names and stories. A purple Monkshood became our Caesar, a scarlet Lychnis our Ajax in defence, and a Lily taller and fairer than its fellows our Cleopatra, and in the little dramas enacted around her we found a counterpart for Antony and Pompey; yes, and for every character in history, mythology and romance, and in the marshalled hosts of the flower-de-luce we saw the banners of France leading an army to drain its lifeblood on eastern sands, in perhaps a fruitless, but nevertheless, noble crusade.

And then, still later, the garden became our rendezvous, its retired sanctuaries the meeting places of friends and lovers. In its shadow-checked ways we discussed the things that were serious to us then, and its knarled and storm-twisted boughs became the recipients of many confidences. In that old garden many a friendship was formed, some that would last us through life—a life of which the sunlight striking through the trees was emblematic, in the carpet of light and shade it cast on our feet.

Again, in later life, when, after the toil and stress of the work of the day, the evening shadows on the mottled sward are infinitely pleasant, and once again we wander with a new interest the paths trodden so often before. The interest now is as far removed from that of our first wonder as we are from what we were then. And just in proportion as our capacity for suffering has increased, so our capacity for enjoyment has grown for the pleasures that the garden now affords. The garden is now to us a place of repose and recreation. The childhood imagery has given place to the worship of pure beauty, but if we are fortunate it has never entirely left us. The denizens of the garden are no longer princesses or jewels, but are still symbolic of them, though they are now something better than either. For as we progress along the way we find that our princesses are not always true, and our jewels are often sham, but the flowers

memories, memories of friends, of places we have known and loved, records of events in our lives told in the spirit language of flowers.

Nor need it be a garden without delight for its own sake. All the joys of a garden can be there, but it shall be redolent with the fragrances of the

almost forgotten past; its walks shall be peopled with the souls of the absent, and its every corner shall be filled with our thoughts, actions and associations; in fact, it shall be to us what our inmost mind is now, a garden of memory.

RAINBOW.

The Cattleyas and Allied Genera

The following notes should be very useful to the many gardeners who have the smallest knowledge of Orchid cultivation.

UNDER this heading will be found the most gorgeous and beautiful members of the great Orchid family, and in many collections they are represented by thousands of species and hybrids. Taking the genus *Cattleya* first, and confining ourselves for the moment to pure species and

Gothard and a host of others. A group that finds favour with many is the outcome of using the small flowered and more highly coloured *Laelias* with certain *Cattleyas*. The individual flowers are on the small side, but this deficiency in size is atoned for in the number of blooms upon a spike, while the colours are brighter and, consequently, more attrac-

THE BEAUTIFUL AND FRAGRANT LÆLIO-CATTELEYA GOLDEN GLOW WHICH RECEIVED A FIRST-CLASS CERTIFICATE FROM R.H.S. IN 1921.

varieties thereof, we find enough material to furnish a display throughout the year. In the Labiata section of *Cattleya* we have such noble species as *C. Mossiae*, *C. Mendelii*, *C. Trianae*, *C. Warszewiczii*, and the superb *C. aurea* and the closely allied *C. Dowiana*. Other species include *C. Bowringiana*, *C. intermedia* and *C. Loddigesii*. The hybrids embrace a wonderful series of fine plants if judged from the decorative standpoint. *C. Iris*, *C. Hardyana*, *C. Rhoda*, *C. Maggie Raphael*, a delightful winter-flowering hybrid, *C. Mantinii*, *C. fulvescens*, and *C. Empress Frederick* are decided acquisitions. The genus *Laelia* does not contain many noteworthy species, and perhaps the best is *L. purpurata*, followed closely by *L. tenebrosa*. The *Laelias* and *Cattleyas* freely intercross, and the progeny is known as *Lælio-cattleya*. One of the first bi-generic hybrids to flower was *L.-c. Dominiana*, derived from *C. aurea* and *L. purpurata*, and it is still in the front rank to-day. Other hybrids belonging to this group are *L.-c. bleckleyensis*, *callistoglossa*, *Canhamiana*, *St.*

tive. Typical of this group are *Golden Oriole*, *Goldfinch* and *Golderest*.

A plant that has played an important part in Orchid hybridisation is *Brassavola Digbyana*, its chief characteristic being the broad, open, heavily fringed lip. This feature has been reproduced more or less in all its hybrids, and now we have a fine group of Orchids with massive petals, large, open-fringed lips, and beautiful combinations of colours which are absent in the *Brassavola* parent. Another plant that has been employed largely is the brilliant scarlet *Sophronis grandiflora*, and there are many hybrids approaching the size of ordinary *Cattleyas*, while still retaining much of the brilliance of the *Sophronis*. The *Sophroncattleyas* are real gems, they are not so easily grown as some Orchids but there is nothing really difficult about them, and the observant, intelligent cultivator will be able to grow them successfully.

Cattleyas and their allies may be grown with other plants in the stove, but if a fair number are cultivated, then a house or division must be set

apart for their accommodation. The temperature should be from 55° to 60° in winter, and from 60° to 70° in summer; the latter figure can safely be exceeded with sun heat. Throughout the dull period of the year the plants will need all the light possible, so the roof glass must be kept clean both inside and out.

During the spring and summer months a certain amount of shade will be necessary, and blinds ought always to be used in preference to any permanent shading. When the weather is bright the blinds should be lowered before the leaves become warm, and rolled up again sufficiently early for the sun to raise the temperature 10° or so. Ventilation is an important item, and a close, stuffy atmosphere must be avoided by admitting air on all favourable occasions. The bottom ventilators running parallel with the hot-water pipes may be open the greater part of the year, even throughout the night. With the top ventilators discretion must be used, and the season taken into consideration to prevent cold currents of air passing immediately over the plants. A moist atmosphere is maintained by sprinkling water on the floor and stages twice or thrice daily, but this applies to very dry and hot weather, and at other times once a day is often enough. Any damping down should always be carried out with a rising, and not a falling, temperature. Excessive moisture and a low temperature are usually the cause of the black spot disease. Various composts have been tried for *Cattleyas*, and undoubtedly the best rooting medium is *osmunda* fibre three parts, and *sphagnum* moss one part. The former is cut up into inch lengths, and the latter is cleansed of all foreign matter, and washed if needed.

The time to repot is often a puzzle to the beginner, and plants are frequently ruined because they are repotted in the spring irrespective of whether they are growing or at rest. With a collection some plants will need attention at intervals throughout the year, and the proper time to repot is when roots appear at the base of the new pseudo-bulb. In some cases new roots are seen soon after growth begins, while with other plants the pseudo-bulbs will be nearly completed. The grower should always wait for them, and, moreover, any repotting should be done before they elongate to any extent to prevent injury when providing fresh soil.

Having selected a plant, it is turned out of its pot, the old decayed soil removed, and dead roots cut off, while the back pseudo-bulbs are reduced to three or four behind each lead or growing point. Ordinary flower pots are chosen, and filled one-fourth of their depth with drainage material. Over-potting must be guarded against, and, as a general rule, enough space should be left for three additional pseudo-bulbs. The compost is made firm, and brought up level with the rim of the receptacle, being neatly trimmed off with a pair of large scissors. Newly potted plants need careful watering; the soil should be kept just moist to encourage root action, and if the weather is bright, a little extra shade will be needed for a few weeks, and a light spray overhead will be beneficial. Rain water ought to be used and it should be made tepid during the winter months. Established specimens that have not been disturbed will take a copious supply of water while growing freely, but when the pseudo-bulbs are fully developed a less quantity will suffice to keep the plants in a plump and rigid condition. Thrips will be present occasionally, and directly they are noticed the house must be vaporised with some reliable fumigant. Scale insects are removed with an old tooth-brush and sponge, but in a healthy collection they rarely make their appearance.

If it is desired to increase the stock of any particular plant, the pseudo-bulbs removed at the

time of repotting may be employed for propagating purposes. Place them in small pots with plenty of small crocks and a little soil on the surface; a stake will be needed to hold them in position. Arrange the pots in a shady corner at the warmest end of the house, and when a growth is formed

re-pot each piece in the same way as you would an established plant. There is no reason why any grower with an average intelligence and a love for plants, should not succeed with Cattleyas. They are as easily managed as ordinary greenhouse plants.
T. W. B.

Winter Irises at Glasnevin

HERE has been an unusually fine display of all varieties of *Iris unguicularis* this season, and many readers of THE GARDEN have recorded instances of early flowering. I send you blooms in the bud stage of four distinct varieties.

Iris unguicularis speciosa is always the first to show buds here. In colour it is a much paler blue than *I. u. marginata* and is more slender and graceful in shape. It is a native of Algiers. *I. u. Imperatrice Elizabetha* has narrow foliage; the flowers are of a lilac tint, the falls broad with a large white blotch lined with darker lilac border; it has a "claw-like" expression. It flowers freely; this season it has not been a single day without blooms since the middle of October.

Very different in habit is *I. u. Lazica*, named from Lazitan, the district in which it was found on the shores of the south-eastern corner of the Black Sea; its creeping rhizome and broad foliage more distinctly ensiform, as opposed to linear, than that of any other form. The colour is a dark purple, the veining being more marked than that usually seen on the Algerian plants. It is the latest of the family to open in this garden; its flowers are usually borne on short stems and are much admired, and desired by slugs.

I. u. speciosa alba is very attractive; the clear yellow blotch on the fall being like a golden eye. The fragrance resembles that of Primroses.

I. u. marginata has no flowers open to-day. It is deeper in colour and larger than *I. u. speciosa*. It is the form most frequently seen in Irish gardens.

Early in January *Iris n. cretensis* began to flower. It was so distinct in colour, shape and size from the other varieties that "The Genus Iris" was taken off the shelf to make all things plain to us. It is a brave, not to say foolish, person who unshreads his or her pen in argument with Mr. Dykes. However, the distance between Vincent Square and Glasnevin is great, and, more comforting still, Mr. Dykes will probably not see these notes, so I boldly venture not to criticise botanical descriptions, but to describe this Iris as it grows here, and as it is seen by a gardener's eye and not that of a botanist. I will quote from Mr. Dykes' noble book: "There seems to be no good reason for separating the Greek (*I. cretensis*) and Asia Minor forms of this Iris from the Algerian plant (*I. unguicularis*) as a distinct species. When Janka first described his *Iris cretensis* he was so intent on showing that it was not *I. humilis*, a plant from the Caucasus under which name Sieber had wrongly identified his specimens from Crete, that he altogether forgot to mention *I. unguicularis*. In any case he would have probably found it difficult to give any differentia beyond mere size by which to separate his *I. cretensis* from *I. unguicularis*. It is undoubtedly true that the Greek plant is smaller than the Algerian, but the two agree in possessing so many characters that are peculiar to them among Irises that they cannot reasonably be separated."

The plant of *Iris n. cretensis* in this garden is abundantly distinct: of close tufted habit; long, narrow leaves; the flowers of a firm texture; falls large, very dark blue, not pointed; a well marked yellow obtuse patch in the centre, netted with white ribs marked at end of the patch by a semicircle of darker blue which separates the variegated lined portion of the fall from the uniform colour. Of the apical portion the standards are distinctly reddish at the base to half way up. Upper part broadly wedge-shaped, much broader than in the type, recurving, so that the whole flower has a much flatter, larger appearance than *I. unguicularis*. The red bases and very pale

THE FIRST SHOW OF THE YEAR

THE Royal Horticultural Society has made a good start with the fortnightly meetings at Vincent Square, for on January 17 there was quite a pleasing variety, much more than the cold and bleak weather would have led one to expect.

From a floral point of view it was the Carnations that held the eye, and these were shown by such regular exhibitors as Messrs. Allwood Brothers, Mr. C. Englemann and Messrs. Stuart Low and Co. Time was, and not so long ago, when Lord Lambourne, the present President of the R.H.S., often sent an exhibit of high quality from his gardens at Bishop's Hall, Romford, and it may, perhaps, be considered an augury for the future that on the present occasion Lord Lambourne was awarded a silver Flora medal for a valuable collection of Carnations. The principal varieties of Carnation to be seen were the new American Laddie and Topsy, with Edward Allwood, Mary Allwood, Saffron, Cupid, Wivelsfield Claret, Wivelsfield White and Carola of the Perpetuals, and Mrs. C. F. Raphael of the Perpetual Malmsons.

Besides Carnations, Messrs. Stuart Low and Co. had a dozen or so little pot plants of the ever-welcome *Daphne indica rubra*, which, even on so cold a day, were deliciously fragrant.

Messrs. Stuart Low and Co. showed very good plants of *Azalea indica* in variety, a useful plant which was also exhibited by Messrs. L. R. Russell, Limited, though their few examples of such uncommon Bromeliads as *Tillandsia Lindenii* and *Vriesea splendens major* attracted more attention on account of their quaint, yet showy flower-spikes.

A delightfully artistic effect was made by Messrs. Carter and Co. with a quantity of the rich blue *Iris tingitana* in uncommon receptacles. *Iris histrioides*, another early species, was to be seen near a few pots of Christmas Roses in the stand by Mr. G. Reuthe; but for the earliest real spring flowers one had to turn to the exhibit by Messrs. R. Wallace and Co., who had Crocuses of the most dainty appearance imaginable. These were of such true species as *C. billorins*, *C. Imperati* and *C. Susianus*. There was just one pot of the earliest Daffodil and some of the varieties of *Erica carnea* which flower before the type. Winter Beauty, Thomas Kingscote and Queen of Spain are all attractive, but not so floriferous as King George, which received an award of merit.

What must really be the last *Chrysanthemum* of the season were shown by Mr. S. Ash, and these were useful blooms of Nagoya (a rich yellow), Winter Cheer (rosy mauve) and The Favourite (white).

A rather nice little rock garden was built by Messrs. William Cutbush and Sons and planted with dwarf shrubs and suitable alpinists. Messrs. Skelton and Kirby also had a small rockery, while Mr. C. Dixon made a neat model of a rock garden adjoining a sunk garden.

Orchids were not numerous, but besides the usual novelties "up for award," there were collections by Messrs. Sandor and Son and Messrs. Stuart Low and Co. The former had an excellent plant of the graceful white *Vanda Watsoni*, which received a cultural commendation, and some beautiful *Cypripediums*, *Cymbidium* and

Odontoglossums. In the collection by Messrs. Stuart Low and Co. there were many interesting *Lalials* and *Brasso-cattleyas*.

Among the exhibits of paintings and preserves there were some vases of *Ornithogalum lacteum* which were given their Zulu name of *Chinke-richees*. These had travelled from South Africa in cold storage, and will continue to open their flower-buds if properly attended to. Mr. K. A. Malby had some of his most beautiful photographic transparencies of specimen flowers, fruits and garden scenes.

Fruits and vegetables were better represented than is usually the case in January. Messrs. George Bunyard and Co. contributed a gold medal collection of wonderfully good Apples. There were seventy-five dishes, and each was unusually good. The fruits were firm, well shaped, and many possessed even higher colour than those Messrs. Bunyard had at the Autumn Fruit Show. Some of the most brilliant varieties were Wealthy, William Crump, Rougemont, Scarlet Hollandbury, Mother and Baumann's Red Winter Reinette.

Sir Charles Nall-Cain sent from The Node, Welwyn, a handsome collection of Apples and Pears. Among the Pears we noted Uvedale's St. Germain, Josephine de Malines, Beurré Alexander, Lucas and Bellissime d'Hiver. The dessert Apples included Cox's Pomona, Cox's Orange, Paroquet, Claygate Pearmain, Blenheim Orange and Adams' Pearmain. This valuable collection received a silver-gilt Knightian medal.

The vegetables were from Messrs. Sutton and Sons, and were of the high quality associated with the Reading firm. The very handsome Leeks, Sutton's At Kale, Couve Tranchuda, forced Dandelion and Chicory, Potatoes and Onions were all excellent.

NEW AND RARE PLANTS.

Erica carnea King George.—This variety differs from the species in that it is more compact in habit and flowers earlier. It is one of the several varieties collected in Switzerland some time back by Mr. Potter, but has until now not received recognition. It was said that the specimen shown had been in flower since last September and it will continue in bloom for a considerable time to come. It has something of the habit of *E. carnea alba*. Award of merit to Messrs. R. Wallace and Co.

Hamamelis japonica rubra.—An interesting deeper-coloured variety, but not so showy as *Hamamelis mollis*, though a decided improvement on the type. Shown by Messrs. R. Wallace and Co.

Chrysanthemum Harlow Bronze.—If only for its lateness, this medium-sized Japanese variety will be valuable. It is also brightly coloured, the bronze having a rosy sheen. Shown by Messrs. Keith Luxford and Co.

Primula sinensis varieties.—There were several good sorts before the Committee. Queen of the Pinks is a bright semi-double variety, Giant White has stellata habit, and the pure white flowers have plenty of substance. Monarch is a rich self crimson variety. All were shown by Messrs. Sutton and Sons.

blue styles, deeply lobed, add to the difference.

Mr. Dykes says *I. u. speciosa* in his experience does not come into flower until March and is of a deep reddish shade of purple. Here, as I have already said, it is the earliest to flower and the palest blue of all.

The plants of *I. unguicularis speciosa*, *I. u. Imperatrice Elizabetha*, *I. u. marginata* and *I. u. alba* were bought from Dammanu of Naples

thirty years ago. The plant of *I. u. cretensis* came from Bitton.—W. PHYLLIS MOORE.

[The flowers Lady Moore sent bore out her contention that *Iris cretensis* is, to the eye of a layman, very different to any of the recognised *unguicularis* forms, but it is equally obviously closely related botanically. Species or subspecies, it is unquestionably a very charming plant.—Ed.]

CORRESPONDENCE

AN INTERNATIONAL EXHIBITION.

FRESH from the hospitality and enthusiasm which signalled the proceedings of the last International Show—I mean the one at Le Mans—and also having been present at many others, I read the paragraph on page 13 with much interest. I do not think the writer fully realises what is necessary to be done to organise an international horticultural show here in London in 1923—that is to say, a show worthy of our great city. The last one took about two years' constant and continuous work of the Committee, which subsequently became the Board of Directors. Probably much of the machinery still exists; certainly most of the active workers are still with us, although death has removed some, notably that splendid chairman, Mr. Gurney Fowler, the like of whom it would be difficult to find again. Another point of great importance is not to clash with big Continental international horticultural shows, and there will certainly shortly be two to deal with, viz., the next Ghent Quinquennial and the next Paris International. Those of us who remember the London Royal International Horticultural Exhibition of 1912 do not forget the large empty area in the section provided for Belgian horticulture—the chief reason of which was that the Belgians had already made preparations for the Ghent Quinquennial of 1913 and could not spare the material to fill the space allotted to them as the Dutch and the French did in theirs. If the Belgians do not allow the war period to count, 1923 is the year due for the next Ghent Quinquennial, but at present it does not appear to have been announced.—C. H. P.

THE CULTURE OF A NEGLECTED RACE OF PLANTS.

THAN the wonderful Tiger Flowers (*Tigridia*) there is nothing more brilliant. Their colour combinations are as daring as anything in nature. Intense crimson, scarlet, yellow, purple, orange, blue and white in practically endless combination

appear, and though the flowers individually are ephemeral, by way of compensation they are produced in succession over a long period. They are especially good for the boxes of sunny windows to breakfast rooms or any room that is only

FLOWERS OF THE HANDSOME TIGRIDIA PAVONIA.

occupied during the first half of the day, as the magnificent flowers are at their best until eleven o'clock. Culturally they are very easy to manage, simply requiring a light, rich soil and a warm, very sunny position. In boxes, or where a special compost can be given them, a mixture of two parts of fibrous loam to one of peat and coarse sand is suitable. Well mix this, and plant the bulbs 3 ins. apart and 2 ins. deep. Each should be surrounded with coarse silver sand, but do not press the soil too hard. Where grown on a border, the best position is under a greenhouse or other wall facing full south on a raised bed. This not only ensures free drainage, but raised soil always lies warmer than that on the level. Wait until the growth is well through the surface, then hoe the soil frequently so as to keep it loose and open,

as this both admits air and prevents evaporation. *Tigridias* love abundance of moisture at their roots and must never be allowed to lack in this respect, or the buds will go blind. After flowering is completed, allow them to remain in the soil until the leaves are quite dead. In wet autumns this is sometimes a difficulty, as they are kept green long beyond their normal time. A spare frame light placed over them is a great assistance in ripening them off, as it keeps the soil drier. When completely faded, lift the bulbs and store away in perfectly dry sand in a frost-proof place until March, when planting time returns.—H. W. CANNING-WRIGHT.

THE HOSTS OF THE MISTLETOE.

FROM time to time I have noticed interesting notes in *THE GARDEN* on the Mistletoe and its hosts, one of these appearing in the issue for January 14th. I once carried out an enquiry on the distribution of this parasite and its host plants, and the results of the enquiry were published in the *Quarterly Journal of Forestry*, Vol. VIII, 1914, page 20. As the result of this enquiry information was obtained of the occurrence of the Mistletoe on various species of *Acer*, *Æsculus*, *Cladrastris*, *Corylus*, *Cotoneaster*, *Crataegus*, *Fraxinus* (including the Flowering Ash), *Juglans* (but only on *nigra*), *Mespilus*, *Ostrya*, *Populus* (but only on the Black Italian), *Prunus* (but only on *coccomilla*), *Pyrus* (but only on *Aria, baccata, Malus and prunifolia*), *Quercus* (on the common Oak twice and frequently on *rubra*), *Robinia*, *Salix*, *Sorbus*, *Syringa* and *Tilia*. No records were furnished of the following trees serving as host plants: Beech, common Walnut, Lombardy Poplar, White Poplar, Plum, Cherry, Pear or Elm; but since 1914 I have heard of its growing on the Plum, the Pear and the Elm. One of the few records of this parasite's occurrence on the Elm is at Charlton Park, Buckinghamshire, so that instances of such cases are of special interest.—W. SOMERVILLE, *School of Rural Economy, University of Oxford*.

CARNATION THIEVES.

AS a sequel to a series of raids on my firm's (Messrs Stuart Low and Co) nurseries at Bush Hill Park, commenced as long ago as November, 1920, two men were sentenced to three months' imprisonment at the Enfield Police Court on January 2. At the Carnation Show in November so many friends asked why our 1922 novelties, Eileen Low and Sir Mackay Edgar, had not been put up before the floral committee, that I was tired of explaining that a few nights previously the thieves broke in and stole the whole of the best of our flowers. I only saved the flowers for the Chelsea Show by sitting up at nights with the foreman, Mr. Ives, and we only secured the thieves at last by continual watching with the assistance of detectives.—LAURENCE J. COOK.

A BEAUTIFUL IRIS.

I HAVE the lovely *Iris unguicularis* in flower at the present time, which I believe I purchased some time ago under the name of *I. stylosa*. The colour of the flower is given as pale blue and light blue in two catalogues, and lavender blue with yellow blotches in two others. I was waiting until mine were in flower again before writing anything as to their colour, but all the blossoms I have seen are a pale mauve, about the same colour as the Neapolitan Violet. I certainly think such a lovely flower as this is, and one which welcomes us in the depth of winter in the open, deserves a better description than "blue with yellow blotches." Both standards and falls are of the same soft mauve tint, made the more delicate by the thinness of the petals. On

the inside the standards have a deep purple, well defined streak at their base, while the base of the falls is a rich light green, shading into a brilliant yellow streak, surrounded by pure white, into which the mauve runs in fine, well marked lines. Over this green, yellow and white zone very fine hair-like dark purple lines radiate from the throat of the flower till they reach the mauve. The three narrow, double-tongued styles are a still paler mauve than that of the petals and contrast most beautifully with the deep purple bases of the standards and the green, white and yellow of the falls, with their perfectly regular and fine radiating lines. It would be well to see this exquisite thing listed under one name and accurately described as regards colour.—H. H. WARNER.

THE EUCALYPTI.

EUCALYPTUS CITRIODORA is, in my judgment, well worth growing for its fragrant foliage alone. We have one here which was raised from seed many years ago in a greenhouse, and was planted out of doors. It is now 30ft. to 40ft. high and has stood unmoved through many heavy gales. I have an idea that its subtle fragrance is healthful in the garden and that it is making good as one sleeps. There is another species, *E. Globulus*, which is also attractive, and no greenhouse or garden should be without these plants. They are easily raised from seed in spring and early summer.—WALTER SMYTH, *Hollywood, County Down*.

SOME UNACCOUNTABLE ANTIPATHIES AND SYMPATHIES BETWEEN PLANTS AND PEOPLE.

HAVE any other readers, I wonder, observed an apparent antipathy or sympathy existing between certain plants and people? It is not a question of people liking plants, but of plants liking people. No; it's not "fancy," but a fact! for it is notorious that even skilled professional gardeners succeed with some plants and fail with others. Have you not often heard folks say, "I never *can* grow such and such," or if complimented on some flower and asked what particular treatment it has been given, "Oh! I never take any trouble with it—it grows quite easily." Now there *must* be some underlying reason for this. Can anyone hazard an explanation? The occasion for this query is our Editor's advice in *THE GARDEN* of January 14 to "sow Sweet Sultan," a flower I have always desired to grow, but it declines my company. I have sown it time and again, but it does not come up. I have bought seedlings in boxes and planted and tended them, all in vain. They sulk and pine away and die, or else survive only in a miserable stunted condition, while in other gardens close by my envious eyes behold Sweet Sultans galore. My mother could never grow Mignonette, much as she desired to do so, nor Lilies of the Valley. My Mignonette spreads in weedy masses, and even permits me to transplant it, and Lilies of the Valley stray out into the pathways. Many find Parsley difficult to grow. Wherever I sow it it does not "go nine times to visit His Satanic Majesty," but comes up quickly and freely; in fact, it seems to follow me like a robin round the garden, for sometimes I find a stray robust rogue in a flower border. *Heuchera sanguinea* will not flower for me (and it's so pretty), *Convolvulus major* is coy in my company, while Canary Creeper and climbing *Nasturtium* love me and try to come inside my open windows. Cornflowers do not care for me (and I do love and desire *true* blue flowers in my garden), but *all* sorts of Daisies do, and I dote on them, from the little double red and white childish one in spring up to Mr. Beckett's tallest and most

magnificent Michaelmas Dames. Poppies and I agree, and Carnations and Pinks of all kinds revel in my society and I in theirs. Bulbs and I are always happy together (I was born in Daffodil-time, at the Vernal Equinox, so no wonder). Situation and soil do not account for these sympathies and antipathies, for I have had eight gardens—town and country, suburban and seaside, large and small, river valley and (as now) some 400ft. above sea-level—and the foregoing experiences have been the same in them all, though some favourites have thriven better in some gardens than in others. Will other readers who have noticed similar likings and dislikings give their experiences?—ANNE AMATEUR.

THE FRUIT OF A BEAUTIFUL CLIMBER

I ENCLOSE a pod of *Araujia sericifera* (syn. *Physianthus albens*) which may interest you. The long, silky filaments attached to the seeds, and from which the plant derives its specific name, are very attractive. My plant is growing on a wall facing south, and has borne about twenty of these large pods this season. The small white flowers are not specially attractive, but their "cruel"

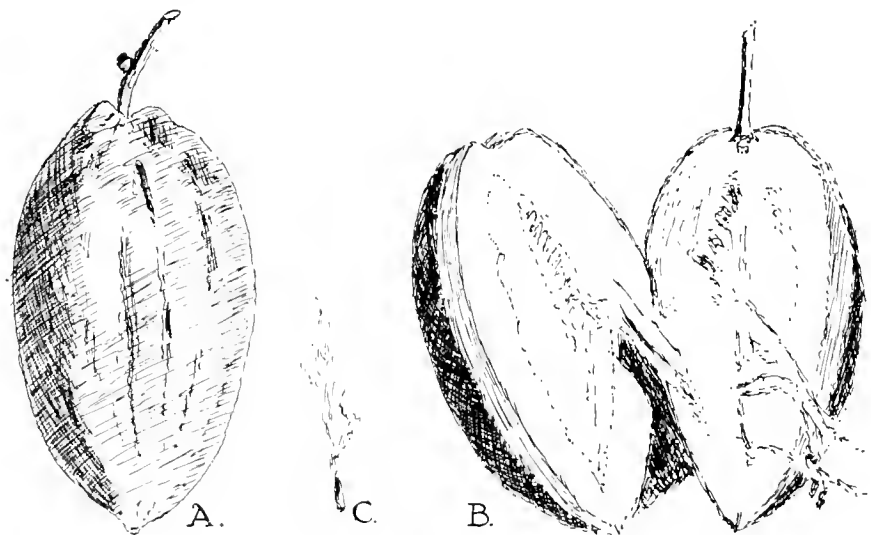

parts of Kirkcudbrightshire and Wigtownshire before December has run much of its course.—S. ARNOTT.

A NATIONAL DAFFODIL SOCIETY?

MAY I suggest to Mr. Engleheart that he ought to get a few stronger nails if he wishes to keep Mistress Daffodil inside her coffin? Perhaps "Somers" could supply him with a few!—JOSEPH JACOB.

"THE GARDEN" AS A BOOK OF REFERENCE.

IT is not too late, perhaps, to suggest that more subscribers to *THE GARDEN* should make a New Year resolution to keep their copies and have them bound at the end of the year. They make such an invaluable book of reference. Having been without home or garden for over two years I have studied other people's gardens whenever possible, and seen many plants that to me are quite new, especially among flowering shrubs and climbers. In my box of favourite books that did *not* disappear "into store" are four bound volumes of *THE GARDEN*, 1916-19

FRUIT OF *ARAUJIA SERICIFERA* FROM THE PLANT GROWING OUTDOORS AT WEST PORLOCK.

A, The great green pod; B, Same fruit split at the suture; C, Seed with its "tail" of silky hairs. (One half natural size.)

habit of catching moths and butterflies by the proboscis is a remarkable one, and it is difficult to see in what way it benefits the plant. Probably the *Araujia* only fruits outdoors in England after hot summers, as it evidently enjoys any amount of sunshine.—NORMAN G. HADDEN, *West Porlock, Somerset*.

"THE FIRST KNOWN DAHLIAS"—A CORRECTION.

ON page 24 in my article on "The First Known Dahlias," there is a little misprint which may mystify the reader. In the second column, twenty-fifth line, it reads "shell on which the flower is mounted." The word "shell" should be *sheet*, meaning the sheet of paper on which the flower is mounted. Four lines lower it reads "Annules du Muséum." This, of course, should be "Annales."—C. H. P.

FLOWERING OF SNOWDROPS.

MY first Snowdrops of the season were in full flower on January 2, an unusually early record for this part of the country (Dumfries). It is not unusual to see Snowdrops in bloom near the Solway and in some of the other mild

inclusive, and in one or more of them I rarely fail to find some reference to these strangers—whence they come, where they may safely be planted, and how they should be treated. These notes are doubly valuable, being usually written by correspondents whose opinion we have come to know and respect. And, of course, old friends are not left out—Daffodils, Tulips, Lilies, Roses, Irises, what you will, they are all there waiting for your consideration.—W. DUGGAN.

BLACK SPOT IN ROSES.

I WAS reading the other day, in an interesting article on *Pernetiana* Roses, that many of the descendants of *Soleil d'Or* are liable to black spot, and I thought my experience might be of interest. I have a large number of *Pernetiana* Roses, and the chief experience so far of black spot that I have had was with *Juliet*. This from the very first leaf it put out in its first year was covered with black spot. A little appeared on the next Rose, *George Dixon*. I gave this *Juliet* away and it has been growing for two years in a Suffolk garden and has so far showed no sign of the disease. I have had none since in my garden.—AMATEUR.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—A sowing should be made to follow the autumn-sown batch. This vegetable delights in an open position and a fairly strong soil, and such should be chosen for the main sowings; but for the present one it will be better if a warm border can be given up to them, so as to hasten them along as quickly as possible. This plant is also amenable to pot culture where room is available, and for this purpose Beck's Dwarf Green Gem is one of the best. Choose pots with a diameter of 8ins. or 9ins. and only half fill the pots at the time of sowing, so that a good top-dressing may be given later. A suitable compost for sowing in would be two-thirds loamy soil and the rest flaky leaf-soil and spent mushroom manure.

Peas.—Choose a warm, well drained piece of ground and make a sowing at the first favourable opportunity, selecting for preference a round-seeded variety such as The Pilot for this sowing. As germination may not be so reliable as later, sow rather more thickly than would be advisable for the subsequent sowings. Sow in shallow drills, afterwards covering the seeds with fine soil. Further sowings should be made in boxes and brought quietly forward under cool conditions as sturdily as possible to make sure of a good succession.

Leeks.—Should plants be required for show purposes or for early kitchen supplies, a sowing ought to be made now under similar conditions to that advised in last issue for Onions, and grown in like manner, unless only a few dozen plants are required, when it would be as well to pot them off singly into 4in. pots when ready, instead of pricking them into boxes as advised for Onions.

The Hardy Fruit Garden.

Spraying.—This important operation is best carried out on mild, calm days, so that the unavoidable risk of the operators getting a little of the wash upon them may be reduced to a minimum; but even then it is necessary for a proper covering to be worn to protect hands, face and clothes. There are thoroughly reliable washes advertised frequently in these columns, and the instructions generally accompanying such should be carefully followed.

Nuts.—These valuable food plants will thrive in almost any garden soil with the exception of a water-logged one, and may sometimes be profitably planted where other fruits do not give very satisfactory returns, such as a very stony position. In selecting a site an elevated one would be preferable to a low-lying one. Planting may still be carried out when climatic and soil conditions allow. The bush method is perhaps the most convenient for Cob and Filbert, but they do quite well as standards or half-standards. When grown in this latter manner it is important to form good head foundations by pruning fairly hard for a season or two. Plant a variety which freely produces male catkins among the others. The variety known as Pearson's Prolific Dwarf has been most favourably reported upon for this purpose.

The Flower Garden.

Annuals as Bedding Plants.—The use of these must be considered conjointly with summer bedding arrangements, for with a great many of the annually raised flowering and foliage plants it is a question of fitting them in to suit requirements, and the selection requires careful consideration. Where there is such a wealth of plants to choose from it is simply a question of meeting individual tastes. In making a selection of annuals for bedding purposes those of proved merit should be chosen. The reserve or other less important parts of the garden should be the trial ground for varieties less well known. Among annuals suitable for bedding purposes pride of place must be given to the Antirrhinum, which, though really perennial, is generally treated as an annual. By making judicious use of a few of the best colours in the intermediate section some really excellent results may be had. The annual Delphiniums, too, make a splendid show when boldly massed, as also do the Lupins. To mention a few others, there are Asters, Alonsoas, Clarkias, Eschscholtzias, Godetias, Nasturtiums (must not be grown on rich soil), Nemesias and P'lox. Especially worthy of note is the Nemesia.

There are but few plants which can approach the brilliant effect produced by a massing of the mixed large-flowered varieties.

Fruit Under Glass.]

Figs.—To obtain early fruits there is nothing better than a few good pot or tub plants, and this method of culture has a great deal to recommend it where space is limited, for such plants may be given a start with Peaches or Vines. Where such is practicable the plunging of the pots or tubs in leaves will encourage a good start by stimulating a healthy root action. Particular attention should be paid to ascertain if the balls of soil of such plants are in an even state of moisture. Avoid extremes of heat, dryness, stagnation of soil and atmospheric moisture.

H. TURNER.

(Gardener to the Duke of Northumberland.)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—In sheltered gardens a sowing should now be made on a warm border for early use. Early Mazagan is one of the hardiest and best varieties for this purpose, while Beck's Dwarf Green Gem is an approved variety where dwarf-growing plants are favoured.

Mint.—Lift a number of roots of this herb and place in boxes for gentle forcing.

Seakale.—Fresh vegetables will now be getting scarce, so occasion should be taken to insert batches of strong forcing crowns at fortnightly intervals and so make sure of generous supplies of this useful vegetable.

Cucumbers.—The present is a favourable time to sow for a first crop. Sow the seed singly in 2½in. pots, using a light, rich compost and braid in the warmest structure available. Kochford's Market is a reliable setter and a heavy cropper for early work.

Fruit Under Glass.

The Orchard House.—Loosen any trees that may be trained to wires on the back wall of the orchard house and have all brickwork lime-washed. Woodwork and glass should also be thoroughly cleansed. The pruning having been done some time ago, the trees on trellis-work must now be carefully trained over and the growths tied in at even distances. The main border of the house where various trees have been planted out should have the surface soil pricked up and suitably top-dressed.

Melons.—Where well heated pits are available, a good sowing of an early maturing variety should now be made. Sow singly in 2½in. pots and plunge in a bed containing a fair amount of bottom heat. Keep the pots covered with a small frame or hand-light until germination takes place. The early crop can be very successfully grown and fruited in pots. The advantage of this method consists in having the plants more under control. The compost should be examined for eelworms and wireworms, and these pests eradicated before the young plants are transferred to their fruiting quarters. Good rich loam with a sprinkling of bone-meal and old lime rubble suits Melons well and should be placed in the house where they are to grow a few days before planting, so that the chill may be taken off the soil.

The Flower Garden.

Preparing Ground for Sweet Peas.—Where Sweet Peas of the highest quality are desired the ground should receive the necessary treatment at this time, provided the climatic conditions are favourable. Trench the ground thoroughly and work in a generous supply of well rotted manure into the bottom spit. Give a light sprinkling of fine grade bone-meal and soot as the working of the soil proceeds, while leaf-mould, old hot-bed manure and wood-ash should be incorporated with the top-spit, as this tends to encourage the young plants at the start, more especially if the natural soil is of a cold, clayey nature.

Roses.—Pillar and climbing Roses should now receive attention in the way of pruning and having the strong growths tied in. The more tender varieties should be left until the end of March, as owing to the variable weather conditions experienced in Northern gardens it is unwise to prune any that are readily injured before that period.

Wistarias.—These desirable climbers should now be pruned and tied in where necessary. Provided the plant has covered the space allotted it, spur-pruning should be practised, as this method has proved most successful in encouraging the necessary ripening of the spurs from which a plethora of flower buds may be expected. If an old growth shows signs of deterioration, train a young shoot up beside it and eventually this may replace it.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Sweet Peas sown last autumn and grown in cold frames should now be ready for potting on into their flowering pots. They require a good root-run, so rain pots should be employed; this is rather a large shift, but it is better to put the plants into their flowering pots now, as they may resent disturbance when they are in full growth later on. Until the plants get well away at the root great care must be exercised in watering. The plants must not be hurried in any way, or the resulting growth will be weak and spindly. They should be stood in a cool, airy house and be given ample ventilation on every possible occasion, carefully avoiding draughts, which are apt to start mildew. The plant should be given suitable supports in time, as they should never be allowed to fall over. When the pots are well filled with roots they should be fed twice a week with diluted soot water, farmyard manure, or guano may be used for a change, using about half an ounce to a gallon of water. Artificial manures should be used with great care and by someone who has a knowledge of them.

Lathyrus pubescens.—This beautiful plant is a native of Chili and Uruguay, and although first introduced in 1840 and again during 1892, is by no means so well known as it deserves. In the West it is hardy when planted against a warm wall. It is by no means a long-lived plant, but is easily raised from seeds, and makes a very beautiful climber for a cool greenhouse. Its pale violet fragrant flowers, which are very freely produced, are useful as cut flowers. I have grown it to perfection planted out on the bench of a Malmesion Carnation house, training the growths thinly to wires under the roof glass.

Lathyrus splendens.—A native of California, this is another beautiful plant that can be grown to perfection under the same conditions as those described above, although it is by no means so good-humoured a plant as *L. pubescens*. When doing well its beautiful crimson flowers are produced with great freedom. This plant, like the former, may be raised from seeds.

Greenhouse Climbers.—The pruning of such plants as require it at this time should now be completed, and at the same time the plants should be untied and cleaned. Plants such as Fuchsias, which if planted out make ideal plants for furnishing the rafters, should be spurred hard back. In selecting Fuchsias for this purpose free-growing varieties are essential. Rose of Castile Improved, Monarch and Lord Roberts are good types to use. Other greenhouse climbers that require to be pruned hard back in the same way are *Solanum Wendlandii*, *Plumbago capensis* and its variety *alba*. *Tibouchina semidecandra* is a beautiful winter-flowering plant, better known, perhaps, as *Ileroma macrantha*. It is seen to best advantage if it can be trained up a wall, as its habit is rather stiff for training under the roof. *Bougainvillea glabra* should also be pruned hard back as advised for Fuchsias. This species is the best one for growing in pots, and where grown in this way the plants, which should have been kept dry during the winter, should now be pruned and started into growth in a warm house.

Abutilons are—or were—favourite plants for planting out in conservatories, but they should be used with care, as their dense habit of growth may prove too much for the plants underneath them. They are well suited for training up a wall, but *Abutilon insigne* is an ideal plant for clothing a rafter, the long slender flowering shoots hanging down in a very graceful manner. This plant has been flowering very freely for some weeks now. *Abutilon vexillarium* and its variegated variety are slender-growing plants also and well suited for clothing rafters.

Hibbertia dentata is an evergreen twiner well suited for a small house, and produces its beautiful yellow flowers very freely during the spring months.

Sollya heterophylla, native of Australia, is a slender-growing climber which produces its

beautiful blue flowers more or less all the year round. It is suitable for training up a pillar or up a wall, where it can get plenty of light. There are many more climbing plants suitable for this purpose, which I hope to refer to in due course, as well as other plants which might with advantage be planted out in the conservatory.

Freesias.—Successional batches should be removed from the cold frames as they are required and be given a light position in a cool greenhouse. The growth should be supported before it falls over, for if once allowed to fall over it never seems to recover properly. Freesias should always be grown as cool as possible. It is true they can if necessary be brought on in heat, but it is always at the expense of the plant and the quality of the flower. As they pass out of flower the plants should be given every attention and not neglected, as is too often the case. They should be encouraged to grow over as long a period as possible, so that strong corns are built up for next season. They can be raised from seed and flowered in nine months' time. That method I will describe later.

J. COURTS.

Royal Botanic Gardens, Kew.

Early Garden Peas.—The gardener, whoever he may be, always takes a pride in raising early vegetables, none of which is more popular than the early Green Pea. Unfortunately many an amateur hesitates attempting to grow a dish of Green Peas by the end of May or beginning of June: first, because he does not think it possible, and, secondly, because the Pea is too often regarded as a somewhat tender plant. The latter is true in regard to the marrowfat or wrinkled varieties, which under ordinary conditions should not be sown in the open until March at the earliest, except, perhaps, in some of the warmer parts of the South. But there is a good tall-growing variety of the round Pea, viz. the Pilot, which if sown during January, preferably towards the end of the month, will yield a good crop by May in any ordinary season. The Pilot is a very hardy Pea and will stand the wet and cold of a bad spring when most other varieties fail. Crops of this have often been ready by Whit Sunday when this festival has fallen due in the last week of May. The Pilot Pea should be sown fairly thickly in well prepared trenches, and small bushy sticks stuck in when sowing is completed in order to afford some little protection when the plant first shows above ground. When this stage is reached a little earthing up is useful, and it is also necessary to protect the crop against the ravages of birds. The Pilot usually reaches 3ft. or 4ft. in height. There is also a very useful Dwarf Pea for early work. This is the Little Marvel. It may be sown fairly thickly in rows across the garden patch towards the end of January or during February, when in a normal season it will provide a good supply of really nice and good-flavoured Green Peas by the end of May or beginning of June.

A Market Grower's Directory and Handbook.—"The Fruit Grower Directory" should be invaluable to all who cultivate fruit, flowers or vegetables for sale or who sell surplus produce. The British classified section contains, among many others, lists of manure and chemical manufacturers, natural manure suppliers, horticultural auctioneers, wholesale and retail seedsmen, fruit growers, market gardeners (under glass and outdoors), fruit-ers, fruit preservers and jam manufacturers, markets, with the salesmen in different departments of each. Potato merchants and nurserymen. There is also a British alphabetical section, and there are also Colonial and Continental sections. Quite apart from the directory proper, there are some sixty-five large pages devoted to useful handbook information, much of which is un-

* "The Fruit Grower Directory and Handbook, 1922," by Benn Bros., Limited, 8, Boulevard Street, E.C.4. Price 10s. net.

obtainable in any other work of reference. No one interested in horticulture from a commercial standpoint should be without this directory.

"Willing's Press Guide."—We have received a copy of this excellent Press Directory for 1922. This is an invaluable book for everyone who contributes or otherwise has any connexion with the Press.

The Directorship of Kew Gardens.—The retirement of Sir David Prain, the eminent botanist, from the directorship of the Royal Botanic Gardens, Kew, has just been announced. Sir David has held the position of director of Kew Gardens for sixteen years. A terrific worker, Sir David seldom moved far from his office, but those who were fortunate enough to meet him were charmed with his delightful personality. Sir David has been very popular with his staff. It is to be hoped that Sir David and Lady Prain may long be spared to enjoy the rest which they both thoroughly deserve. Dr. Arthur W. Hill, who has been assistant director since 1907, has been appointed director. Dr. Hill was, before he went to Kew, lecturer in botany at Cambridge University and Dean of King's College, Cambridge. He has travelled a great deal and has recently returned from an official visit to Nigeria. A keen sportsman, Dr. Hill is very popular, especially with the student gardeners.

Chelsea Show.—All those who intend to exhibit rock or formal gardens at Chelsea, May 23-25, 1922, and who have not already received a communication from the R.H.S., should communicate with the secretary at once.—W. R. DYKES, Secretary, R.H.S.

Royal Caledonian Horticultural Society.—The syllabus of the series of monthly meetings of this Society has been issued, and the list of lectures, etc., is of great promise for a successful session. Among the lecturers are Sir Herbert Maxwell, Bart., who will give "Cultural Notes on Rhododendrons"; The Brodie of Brodie, who will lecture on "Daffodils"; and Mr. Osgood H. Mackenzie of Tournaog, Poolewe, who will tell of some of the exotic plants with which he is so successful in his wonderful garden in Ross-shire.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

HYBRID HELLEBORES (M. L. T.).—We have no knowledge of the Hellebores grown by the gentleman in question, but if they are the hybrids of *Helleborus orientalis* (Lenten Roses), originally sent out by Heimenann, these are obtainable from Messrs. R. Wallace and Co., The Old Gardens, Tunbridge Wells, and probably from other firms.

SOIL REQUIREMENTS OF GENTIANAS (H. A. G.).—Most of the Gentians mentioned, which are rather coarse species, should flourish in your well drained sandy loam, rich in humus. They require, to flower full sunlight and the addition of sphagnum moss to the top 6ins. or 8ins.—say, one part of sphagnum to four of soil—would be an improvement. These plants are weeds on some soils; on others, apparently similar in composition and aspect, they fail. This is attributed nowadays to the presence or absence of a fungus with which their life history is bound up. Of the list given, *ascendens* is a synonym of *decumbens*, while *Freyriana* and *Lagodeschana* are forms of *septentrionalis*. All three are welcome denizens of any garden. *crucifera*, *decumbens*, *Kesselringii*, *macrophylla*, *cranem*, *phlogifolia*, *punctata* and *tibetica* all run rather to foliage than to flower and are only desirable to the collector. *Przewalskii* and *purpurea* are choice, but not easy to grow; while *Sajonaria* is a North American woodland species, so should have partial shade. *Dungei* and *Matrix* we do not recognise, but *Wagenii* is perhaps *Wahjawi*, which is easy enough to grow, but of no garden value.

THE GREENHOUSE.

TREATMENT OF BULBS IN POTS (L. E. M. S.).—Provided the soil is moist and well drained, poorness will have no effect on the flowering of the bulbs this year. Nutrition for this purpose is stored in the bulbs the previous season. Probably our correspondent kept the soil too dry in the early stages of growth. Even if plunged

in ashes outside, watering was necessary this season owing to the excessively dry weather.

HAEMANTHUS ANDROMEDA (A Devonshire Reader).—This plant is a hybrid between *H. Katherine* and *H. magnificus*. The popular name is the Blood Flower, not Blood Root. The plants will grow in a cool greenhouse, but a little higher temperature than that usually associated with a cool greenhouse is preferable. As a potting compost use equal parts fibrous loam, peat, leaf-mould and coarse sand. The plants flower better when grown in comparatively small pots for the size of the bulbs.

RAISING MESEMBRYANTHEMUMS (W. R. J.).—These plants require an exceptionally warm and sunny position and porous, gritty compost. It would perhaps be preferable to raise the seedlings in a frame, but beyond this the plants would probably thrive on hot, sunny slopes in our correspondent's favoured county of Cornwall.

MISCELLANEOUS.

WEED IN LAWN (R. A. B.).—The weed is the Staghorn Plantain, a native of sandy soil. A pinch of sulphate of ammonia put upon the crown now or any time till mid March will probably kill it outright and will assist the subsequent growth of grass.

USE OF GRANITE TO IMPROVE SOIL (W. R. J.).—We think the shale in the soil should drain it sufficiently if there is means below for the removal of surplus water. If not, the soil should be drained by means of pipes which will carry away the surplus water. No amount of granite would enable water to drain away if the subsoil retains water. The granite might be used for rock-plant soil so long as it is certain that it contains no arsenic. Some of the Cornish rocks are too well supplied with that poisonous material.

BOOKS BY PLANT COLLECTORS (C. B. U., Kirkdale).—There is no bibliography dealing specially with books recording the travels and adventures of plant collectors. Some particulars regarding such collectors and their works are given in Britten and Boulger's "Biographical Index of British and Irish Botanists" (London: West Newman, 1893) and its three supplements, which were published in the "Journal of Botany," 1898, 1903-4 and 1908. The catalogue of the Library of the Royal Botanic Gardens, Kew, would also afford help for the works on travel. Many of them by naturalists are listed separately. The Catalogue is sold by Messrs. Gale and Pollen, Royal Botanic Gardens, Kew, price 8s. 9d. post free; Supplement, price £1 ls. post free. The following are some of the most important books on travel by British and Irish naturalists, including plant collectors: "Journal of Researches, A Naturalist's Voyage," by C. Darwin, 1839 and other editions. "Himalayan Journals," by J. D. Hooker, 1854 and other editions. "Journal During Captain Cook's First Voyage," by Sir Joseph Banks (edited by J. H. Hooker), 1896. "Notes of a Naturalist in South America," by John Ball, 1887. "Three Years' Wanderings in the Northern Provinces of China, etc.," by R. Fortune, 1847 and 1857. See also other books by Fortune. "A Naturalist in Western China," by E. H. Wilson, 1913. "The Land of the Blue Poppy," by F. K. Ward, 1913. "On the Eaves of the World," by R. Farrer, 1917. "Journal During his Travels in North America, 1823-27," by D. Douglas, published by the Royal Horticultural Society, 1914.

NAMES OF PLANTS.—J. M. Co. Wicklow.—*Colletia cruciata*. This is not a true species, being really a form of *C. spinosa*.—"Verney."—The plant sent for identification is *Ornithogalum laetum*, a South African bulbous plant known in its native habitat as Chinkerieches and also as Pigeon's Milk. This plant may be grown in England in a conservatory. Propagation is carried out by means of the offsets.—A Devonshire Reader.—*Trachelium coruleum*.—A. E., Shalford.—*Cypripedium insigne*, a native of Nepal, this plant flowers every winter and will grow in a temperature of 50° to 60°.—E. S., Sussex.—*Linaria Cymbalaria* (Ivy-leaved Toadflax).—A. H. S., Guildford.—1. *Lonicera Standishii*; 2. *Juniperus chinensis*; 3. *Sequoia sempervirens*; 4. *Abies* sp. (specimen not in character); 5. *Cupressus Lawsoniana*; 6. *Tsuga mertensiana*; 7. *Abies Nordmanniana*; 8. *Pinus Laricio*; 9. *Cupressus Lawsoniana* var. *erecta* var. *viridis*; 10. *Sequoia gigantea*; 11. *Pinus excelsa*; 12. *P. Cembra*; 13. *F. sylvestris*; 14. *Pinus* sp. (specimen too poor); 15. *Cupressus Lawsoniana* var. *lutea*; 16. *Juniperus chinensis* var. *aurea*.

NAMES OF FRUIT.—A. H. S., Guildford.—Apples: 1. *Cellini*, late fruit; 2. *Lemon Pippin*; 3. *Cockle Pippin*; 4. *Waltham Abbey Seedling*. Pear too decayed to identify.—New Reader, Windermere.—Apple *Christmas Pearmain*.

NOTES OF THE WEEK

[FEBRUARY 4, 1922.]

SWEET PEAS IN BLOOM.

Like sunset clouds that cluster in the west
When the daylight passes on and night descends;
Like cheeks of children laid in Dreamland's quest,
Against soft pillows when the twilight ends.

Like a veil of purple mist above the sea,
Low trailing where the sky and ocean meet,
Trembling to life at Daybreak's witchery—
Or like a pink shell crushed by passing feet.

No canvas half so rare as this could be;
No human hand could scatter tints so fair,
For in the Crypts of dreams and imagery,
No Artists live like Sea, and Sun, and Air.
San Francisco Bulletin. JACK BURROUGHS.

An International Show?—In last week's issue Mr. Harman Payne called attention to the length of time necessary to organise an International Show. It must be remembered, however, that much of the organisation and machinery appertaining to the last "International" is still in existence. This being so, it seems to us that it should easily be possible to carry out the Show in 1923 if steps be taken at once to proceed with the idea. It is true, of course, that enquiry needs to be made as to Continental fixtures, but to us 1923 seems much more likely to be free than 1924 or 1925, for instance. In any case, it is evident that it is high time thought was given to this question of an International Show.

The Postal Muddle.—Even the daily Press has been discussing the action of Messrs. Bees, Limited, in posting and—should we add?—printing their catalogues in Germany. There is, it is scarcely necessary to say, great difference of opinion as to the merits or demerits of the scheme in question. One party calls it "sordid commercialism," while another considers their action truly patriotic. Be this as it may—whatever the intention—the firm has certainly done good

service in once again calling attention to the anomaly that German firms can send literature here for a tiny fraction of the charge levied on the British producer or merchant. Another anomaly to which attention should be drawn is the singular arrangement by which magazines may be sent by post from London to the wilds of Alberta or Saskatchewan for less than from London to Reading! The Post Office is, in fact, trying to conduct its business on a system which if applied to any industrial concern could only mean speedy bankruptcy. Instead of a big turnover at a reasonable rate, which would foster trade and at the same time increase revenue, this misguided department has ever since the war been intent on a small business at an exorbitant price. The telegraphs still lose money, and the telephones, despite the heavy rates in operation, are none too efficient, and it is very doubtful if, even now, they are paying their way; yet the National Telephone Company before the Government "took over" was a prosperous and progressive concern. Its operations, however, were unfettered by red tape!

Agitate!—There is no need to make apology for once again bringing this question forward into the light of day. Dear postage, in all probability, hits the horticultural trades as badly

as any, and worse than many, and, though the public sometimes fail to realise it, heavy incidental expenses such as these must ultimately come out of the pockets of the purchaser. There is some hope that if a really strong protest is voiced, some relaxation of the present heavy impost may be afforded. The password for all who would shift the burden should be "Agitate!"

The Rose and the Thorn.—"Gather ye Roses while ye may!" Ay, but Roses have thorns, so where are the gardening gloves? There are on the market various devices for gathering flowers. An excellent one recently marketed is the Plucca pruner, which, in addition to being an excellent pruner with a detachable blade made of sword steel, has an attachment (easily removed if not required) which enables one to gather Roses without fear of thorns, or flowers, at arm's length, without danger of dropping and soiling or bruising them. It is made in three sizes, the smallest suitable for pruning Rose trees and small enough and light enough for a lady's use, while the largest is strong enough for quite heavy pruning. The design is simple and straightforward, there is no possibility of pinching one's fingers—a common fault with many otherwise excellent secateurs—and, a particularly good point, every part is standardised and there is offered a complete set of replacement parts in case anything wears out or breaks.

Prune and Tie Up.—It is now a reasonable time to speak of pruning tools, since with the advent of February fruit-tree pruning should no longer be neglected. In the case of wall fruit trees, pruning will need following by tying in. Here consideration might well be given to the Everyman wall-clip, which represents the latest idea in this direction. With this the nails do not break, nor can the clips, once the nail is driven, become detached. It is immaterial in which direction the clip lies when the nail is driven, since it clips loosely and may be turned in any desired direction.

SWEET PEAS IN BLOOM.

SOME PERENNIAL PLANTS FROM SEED

Always a fascinating pursuit, the raising of perennials has in many gardens become a necessity from reasons of economy.

IT is unwise to postpone the sowing of such things as hardy Primulas until this season, as their germination is far less certain than if they were committed to the earth immediately they were ripe. There are, however, many perennials which are readily raised from seeds sown now, and it is not always, or indeed often, convenient to sow perennial seeds generally as they ripen. Again, in the case of varieties which it is desired to try and of which the seed must be bought, it seldom happens that one gives them a thought until, about New Year's Day, seed lists come to hand.

Some seeds are bought because the species or variety come true from seed; others, strangely

one is ambitious to raise new varieties, it is better in their case to leave seed-raising alone.

Seeds are the natural and proper means of increasing Aquilegias, but if the beautiful species are wanted true it is useless to save seeds from one's own plants. Reliance must be placed upon collected seeds purchased through some reliable seed-house. With the old-fashioned garden Columbines or the newer long-spurred hybrids the case is, of course, different. Here interest attaches rather to the immense variety than to their reproducing true. The seeds of these plants are very hard, and abundance of water is needed until germination takes place. This necessarily involves nicely textured soil and good drainage to begin

pod of a good persicifolia form is remarkable. These seedling forms have an abounding vigour very grateful to the gardener. Persicifolia is one of the readiest plants to increase by division, so that, except for new forms and increased vigour, it need not be raised from seed, but with *C. lactiflora* the case is different. This is a plant rather impatient of propagation. From seed many of the plants will lack the just colouring which everyone admires, but if the seeds were saved from the right form a percentage will come true, and the plant is so beautiful intrinsically and a few specimens will ultimately make such a fine clump that the trouble is well repaid.

Of the smaller species—many of them alpine—numbers are offered as seed from the ever-useful *carpatica* and the daintier *turbinata* to those minute alpine jewels *Waldsteiniana* and *Zoysii*. All the tap-rooted species, such as *Portenschlagiana* and *garganica*, should occasionally be renewed from seed, as the seedlings have a vigour very pleasant to see, as they spread from the rock-bound fissure in which their roots dwell, right across the massy boulders on either hand.

Seed is often offered of *Chrysanthemum maximum* usually So and So's "giants" or "Goliaths." The flowers from such strains are usually abominably rough and coarse. The wise gardener will, if he wants to try his hand at raising a new variety—and it is not easy—hybridise flowers of really first-rate kinds himself.

Few will wish to raise *Galega* from seed in all probability, but in case any do, it is worthy of mention that *G. carnea pleua*, which is a very distinct and pleasing form, appears to come true from seed.

All the *Hypericums* come true from seed, and of them the name is legion; but unless extensive naturalising is contemplated, few will trouble to raise any except those beautiful trailers *repens* and *reptans*, which, though very distinct, are both invaluable for the rock garden.

The Torch Lilies—*Kniphofias* or *Tritomas*, as they are still often called—come readily from seed. *Uvaria grandiflora* is the variety usually listed, but the beautiful Express hybrids are often offered, and such remarkable and valuable species as *nobilis*, *caulescens*, *Northiæ* and *Tuckii* also may be obtained. These and, where space is limited, the charming little *pauciflora* forms are best worth attention.

Very easy to raise and very beautiful when raised are many of the Toad-flaxes (*Linaria*). *L. macedonica* is probably the best of the taller forms, while most of the trailing kinds are so readily propagated as hardly to be worth the trouble of raising from seed. This, however, does not apply to the beautiful *alpina* and its forms. This species is in our climate little better than a biennial, but it is so exquisite that few will grudge the slight labour of raising it. Indeed, on the moraine it will often naturalise itself from self-sown seed.

The true Flaxes are peculiarly suitable for cultivation from seed. They are readily raised so and difficult effectively to propagate otherwise. *Linum perenne*, *L. narbonneuse* and *L. alpinum* are invaluable, the last mentioned a gem for the rockery, but the pale yellow-flowered *arborescens* has many admirers.

Fairly easy to germinate and facile enough in really gritty compost is that quaint Cress, *Morisia*

IF PLANTS OF *CAMPANULA PORTENSCHLAGIANA* (*MURALIS*) ARE WANTED TO SMOTHER THE ROCK FACE IN THIS WAY, RECOURSE SHOULD BE HAD TO SEED-RAISING.

enough, because it does not. All the *Gypsophila* species may be considered to come true from seed, including the invaluable *paniculata* and the choice alpine *cerastioides*. The seedlings of *paniculata*, however, usually come, some with green stems, some with wiry black ones, which latter are, of course, more welcome. If plants be bought, however, they may very probably all turn out to be the green-stemmed kind. Even the double form of *G. paniculata* gives a fairly good percentage true from seed, while the remainder are, of course, the useful, if more ordinary, single kind.

Almost all *Geums* come true to colour from seed, and the alpine species, of course, come true. There are some very woody strains of *Geum* Mrs. Bradshaw on the market which have come about by saving seeds from unselected seedlings. This plant tends to lose size and character from seed, and unless re-selected it progressively and rapidly deteriorates. *Anchusas* do not come quite true from seed. They are readily and rapidly increased by means of root cuttings, so that unless

with, as *Aquilegias* by no means appreciate sour soil.

To those who contemplate raising Michaelmas Daisies from a casual packet of seeds, the best advice is, *don't*. The plants resulting are almost invariably dreadful weeds. If the spirit moves one carefully to cross-pollinate some of the varieties in one's garden, that is another story, though even then a large percentage of absolute "duds" must be looked for.

Easy and valuable plants to raise from seed are the *Bocconias*. Of the two species, both decorative, *cordata* is handsomer in creamy panicles, but *microcarpa* is the stately and has a little the nobler foliage.

Campanulas in general well repay the raising of any form worth growing. Some of the herbaceous species are, as most gardeners know, rather ineffective and "dead-nettley" in appearance, but it is well occasionally to raise the really worthy species from seed. The number of distinct forms and shades of colour which will come from a single

hypogæa. This is a really invaluable plant in hungry, well drained soil or, preferably, on the moraine.

Readily raised, so that the seeds be not smothered, the various species of *Mimulus* are so easily propagated by division that few will trouble to raise them. Very different in this respect are their water-loving neighbours the *Lythrum*s, which are easy to raise and come wonderfully true to type. The rose-coloured forms alone are usually grown in gardens, as few people like the rather startling magenta of the wild plant. The *Statice*s, again, are easy to obtain from seed, and if some of the plants of *S. latifolia*, for instance, lack the rich colouring of the best forms, they are not altogether wanting in charm.

The Meadow-Rues (*Thalictrum*s) form another family profitably raised from seed. *Aquilegifolium purpureum* and (especially) *diptero-carpum* are probably the best; but all are beautiful and, for the diversity they introduce, very useful in the mixed border. Such *Verbascum*s as *Miss Willmott*, which, however, throws a percentage of soft yellow forms, and *Harkness's Hybrid* should be obtained from seed, as should *V. phœniceum*, with flowers in many shades of lilac, rose and purple as well as pure white.

The herbaceous *Speedwells* (*Veronica*) are, generally speaking, easy to propagate vegetatively, also few of them come even approximately true from seed. The amateur, then, will be wise to pass them by when making out the seed order. The same remarks will apply to the hybrid *Erigeron*s, while no one not excessively fond of trouble will try to raise any of the true *Thistles* (*Eryngium*) except that fine biennial species *E. giganteum*. The *Globe Thistles* (*Echinops*), on the other hand, are readily raised and very handsome, and so are the alpine *Carlina*s, *acaulis* and *acanthifolia*. Of these the latter is the more worthy species. The sessile straw-coloured flowers in the centres of the great silvery rosettes are very remarkable. Strangely, *acaulis* is not, even on the Alps, stemless. The rosettes are handsome enough, but it becomes an ugly weed when it runs up to flower.

It is strongly to be recommended to raise most true alpine immediately the seeds are ripe. This particularly applies to such genera as *Gentiana*, *Primula*, *Anemone*, *Soldanella*, *Shortia*, *Pinguicula*,

THE CHARMING FORM OF THE CARPATHIAN BELL FLOWER USUALLY LISTED AS *CAMPANULA TURBINATA*.

and perhaps *Androsace*. It applies less forcibly to the last named genus, also to *Lithospermum*, *Onosma*, *Mertensia* and *Helleborus*, which take longer to germinate if kept, but do not so rapidly lose vitality. *Alyssum*s, *Aubrietia*s, *Æthionemas*, *Arabis*e—few will care to raise any but the choicest, such as *Sturrii*, *procurrens* or *Ferdinand-Coburgi*—*Drabas*, *Erodiums*, *Geranium*s, *Erysimum*s, *Iberis*e, alpine *Pinks* of sorts and the mossy *Saxifrage*s. The *Kabschia* and *Eu-aizoon* (*Encrusted*) forms of *Saxifrage* are quite raisable now, but, being choice, should wherever possible be given the best possible chance by sowing early—preferably as soon as ripe or obtainable from the collector. No reliance can be placed on home-grown seeds of the encrusted *Saxifrage*s coming true to type.

Almost invariably the seedlings prove to be natural hybrids of some kind. This to many people, however, affords but an additional fascination.

So far, broadly speaking, we have been considering plants which are recommendable to raise from seed because they come true. Incidental mention has, however, been made of such plants as the long-spurred *Aquilegia*s, which are valuable and interesting owing to their kaleidoscopic variations in colour. Another race of plants which makes a similar appeal is the herbaceous *Lupin* (*Lupinus polyphyllus*). The *Lupin*s, under the magic wand of the hybridist, gradually been translated until what used to be rather unattractive plants, with spires of purplish blue or dirty white, are now almost endless in variety and glorious in purity of colour. Rose pink, buff, yellow, mauve, blue and white all enter into the coloration of a good strain, some in practically self colour, the yellow and buff particularly in combination. Some of the forms charm by their seeming delicacy, alike of form and colouring. Others of more robust colouring make an equally sure appeal in their combined brilliance and purity.

*Gaillardia*s are readily raised from seed, and though the colour range is limited, yet the variations in form and to an even greater extent in arrangement of the colours are remarkable. These plants are apt to die out on some soils owing to winter wet. Where such is the case it will be found that the superior constitution of the seedlings is invaluable.

Seedling *Delphinium*s, even if raised from seed from one plant only, show considerable variation. Like the *Gaillardia*s, they have a vigour alien to the too often over-propagated named kinds, and it is wonderful how satisfactorily the very diverse colours group together.

Few plants are more easily raised—albeit not over-quick to germinate—than the hybrid *Pentstemon*s, which make so brave a show in late summer and autumn. If seed be bought of a really reliable strain, a large proportion of the seedlings will be really first-rate. They should include varieties of almost every shade of colour

THE HERBACEOUS LUPINS (*LUPINUS POLYPHYLLUS*) HAVE NOW AN EXTRAORDINARILY WIDE AND BEAUTIFUL RANGE OF COLOUR.

from all but pure white to crimson-scarlet in one range and to purplish maroon in the other with wide throats and huge flowers. Such results cannot be expected, however, from cheap seeds, as really good varieties seed but sparingly.

Methods of procedure calculated to assist and forward germination were mentioned in an article on perennial seed raising in *THE GARDEN* for December 24 last, so that there should be no need

to recapitulate. It may be worthy of note, however, that the Giant Parsnips (*Heraclium*), at all times slow to germinate, are all but impossible to raise within a finite time unless sown immediately the seeds are ripe. Like those of the Lotus of the Nile, the seeds seem to retain their vitality for a long time, but it is exceedingly difficult once they get thoroughly dry for moisture to penetrate to the germ.

ANNUALS FOR THE GREENHOUSE

The hardy and half-hardy annuals as used for greenhouse decoration are very effective and represent one possible method of economy in these days of dear fuel.

FOR a good many years now annuals, both hardy and half hardy, have steadily been increasing in favour for furnishing the greenhouse and conservatory. Tender annuals have, of course, always been largely used for this purpose. Some twenty-five to thirty years ago numbers of hardy and half hardy annuals were regularly grown for the conservatory or show house in the Royal Botanic Gardens, Kew, and the writer well remembers how many gardeners used to scoff at the idea of growing annuals in pots; and that, in spite of the fact that market men had regularly grown some favourite plant, such as Mignonette, for many years previously. The idea that such plants required no care in cultivation was a mistaken one, as many gardeners discovered when first they took up their cultivation. It is true that, given the right conditions and a knowledge of the plants, their successful cultivation presents few difficulties to a good grower. The gardener must know his plants, however; he must, for example, know which can safely be transplanted and differentiate them from the remainder, which will not stand pricking off with any degree of safety, and which must, therefore, be sown directly into their flowering pots. The cultivator must also bear in mind that any check, whether it be from over-watering or from dryness at the root, or, in fact, from any cause, will usually prove fatal, or at any rate, the grower will have very little chance of getting the plant into a healthy condition such as he would have with perennials. The life cycle of annuals, in fact, covers such a short period that there is little time for them to recuperate, so that if a batch of plants go wrong they might just as well be thrown away.

In speaking of this class of plant growers usually use the term "annual" in its broadest sense, frequently applying it to plants that are truly biennial, and in quite a number of cases really perennial. In a sense the term is correct when applied to any plant that for a particular purpose can be raised from seed and flowered within the same year. On the other hand, a good many annuals used for this purpose are treated as biennials being sown the previous year to that in which they are flowered, with this difference, however, that they are not sown so early as those which one regards as true biennials.

Now as to the essentials for successful cultivation: For most of them it is quite simple, needing merely cold frames and, as they approach the flowering stage and require more head room, cool houses. If the frames and houses are heated so much the better, not that much heat is required or even desirable, but during a spell of dull, damp weather it is often an advantage if a little heat can be turned on for an hour or so to dispel moisture and change the atmosphere. Generally speaking, however, the cooler they can be kept, with plenty

of air on all favourable occasions, the better will be the results. The chief aim should be to keep the plants strong and sturdy; but this is not always so easy as it would at first sight appear.

THE GODETIAS WITH THEIR SILVERY SHEEN ARE EXCELLENT FOR CULTURE UNDER GLASS.

A long spell of dull, sunless weather often results in weak and spindly growth. Again, not all houses are well adapted for growing successfully this class of plant; remember that plenty of light and air is essential, and at all stages of growth it is an advantage if the plants can be kept as near the roof glass as possible. As regards the time of sowing, there is no doubt that for some plants autumn is the best time, especially if fine large specimens are desired, but good results may be obtained by sowing almost all annuals now. This applies especially to such popular things as Mignonette, Clarkias, Godetias, Schizanthus, Larkspurs, Nemesias and Viscarias.

While autumn sowing is desirable and in many cases gives the best results, especially in the country where there is plenty of winter light, on the other hand, in the immediate neighbourhood of London and other large towns success is by no means so certain; this is mainly due to fogs and lack of light. It is hardly possible to keep them from making growth, and this is often so weak that it is not capable of supporting itself; needless to say, such plants take some time to recover when

better weather conditions do prevail early in the New Year. On this account we find at Kew that it is best to defer the sowing of most annuals for pot-work until the days commence to lengthen. It is true the resulting plants are not, as a rule, so large, but they do at least have a chance to make decent growth under the better weather conditions.

The maintenance of proper temperatures is important, and the chief thing to avoid is too much heat, bearing in mind that many of these plants are hardy and will stand outdoors, except, perhaps, on very heavy and cold, wet soils. Although in these cool conditions they may not make much top growth, they are, nevertheless, very active at the root. The temperature may fall, therefore, to freezing point—although this is not desirable—without any harm resulting. They should be kept at a steady temperature of 40° to 45° with plenty of air on all favourable occasions, taking care to avoid draughts, which are more harmful than a low temperature.

The temperature during the day may be allowed to rise 5° to 10° with sun heat without any harm resulting always provided ample ventilation is given.

Watering, needless to say, should be carefully done during the dull days. The seed pans or boxes should be made moderately firm; many cultivators err in this respect, making their seed bed too loose. In a loose medium, damping off is generally more troublesome, and in dealing with this class of plant damping off has generally to be guarded against. For this reason the seed should always be sown very thinly, and the resulting seedlings pricked off before they become crowded. In most cases the young seedlings are best pricked off directly they are large enough to handle into 48-sized pots; if larger pots are required they can be potted on as they require it. Whether they are grown singly or several in a pot depends largely on the variety of plant used. Again, some may require stopping or pinching to induce a bush habit; with others this is not necessary; in fact, some would not stand it. For example, Clarkias, Godetias and Schizanthus may be grown singly in pots, and generally with advantage may be stopped; whereas such slender growing things as Viscarias and Linarias will require five or six plants to furnish a pot properly.

No artificial manures should be added to the potting soil, but when they have well filled their flowering pots with roots and are growing freely they will benefit by frequent applications of clear soot-water and diluted liquid manure; guano, which is a safe, all-round fertiliser, may also be used at the rate of 4 ozs. to a three-gallon can of water. In applying manures it is always safe to use them weak and often.

The foregoing remarks on the cultivation of hardy and half hardy annuals in pots applies generally to the more tender greenhouse annuals, with the exception that they for the most part may with advantage be grown in a higher temperature. Celosias, for example, are best grown in a temperature of 50° to 60°. All of them, of course, when in flower, will stand in the cool greenhouse.

A short list of the various sections may prove helpful to readers who have not yet attempted the cultivation of this class of plant. The following may with advantage be sown now: Mignonette, Clarkias, of which there are now many fine varieties; Godetias, especially Schamini fl.-pl. and variety Rosy Morn; also Godetia Lavender. I cannot understand why this beautiful variety is not more generally grown. It is, I suspect, an improved form of *G. tenella*, or to be correct, (*Enothera tenella*), as all Godetias are now botanically included in *Enothera*. Antirrhinums, although not

A BORDER OF HARDY ANNUALS

Being "Somers'" promised further suggestions for its planning.

strictly annuals, will give good results if sown now. Sweet Peas, Schizanthus, Viscarias, Nicotiana Sanderæ, Delphinium Ajacis vars., the tall, branching Rocket Larkspurs, also the beautiful Stock-flowered Rosy Scarlet

In addition to the above the following may be sown now: Alonsoas, Browallia elata, blue and white; the dwarf forms of Coreopsis tinctoria, Chrysanthemum carinatum varieties, also C. segetum vars. Morning and Evening Star; Collinsia bicolor and candidissima, Gilia dianthoides, Helichrysums, Kochia trichophylla, for its foliage; Mina lobata, which may be trained up the roof; Nemophila insignis, which makes pretty baskets; Scabiosa atropurpurea, in many varieties; Schizanthus, of which there are many fine strains; also S. Wisetonensis and S. retusus, Statice Suworowi and S. sinuata, both blue and white; also Nemesia strumosa and N. Blue and White Gem.

Annuals that do not transplant readily but should be sown directly into their flowering pots are Mignonette, Acrocliniams, rose and white, very elegant everlastings; as also are Rhodanthe Manglesii and R. maculata, in rose and white; Hunnemannia fumarifolia, a beautiful Poppywort from California, is generally classed as a biennial or a short-lived perennial, but in this country it behaves as a hardy annual; Meconopsis heterophylla, the Sweet Sultans for which calcareous soil is essential, and Salpiglossis which can certainly be transplanted, but they are one of the most difficult of annuals to do well, so that it is wise to sow directly into their flowering pots.

The term greenhouse annuals, as generally used, is a pretty wide one, and may be applied to such plants as the Chinese Primula or Cineraria, which, if sown early enough, will flower the same year. Most so-called greenhouse annuals are—in the South at least—half hardy, that is, they will stand outdoors during the summer if they are raised indoors and then planted out. Some of those which are used for greenhouse decoration during summer and autumn are Amaranthus tricolor splendens, Aselepias curassavica, and Begonia semperflorens in many fine varieties may be treated as annuals; Browallia speciosa major, Celosia cristata and var. pyramidalis, Impatiens Balsamina (Balsams), I. Holstii and I. Sultani may also be treated as annuals, as may Ipomœa rubro-cœrulea, a beautiful blue-flowered climber; Lobelia tenuior (all the Lobelias may, in fact, be treated as annuals), Petunias, Thunbergia alata, Torenia Fournieri and T. Bailloni, also Exacum affine. The lists given are by no means exhaustive, but will serve to show the wide range of plants that may be used in this way for greenhouse decoration. Where only a very small and low house or houses are available there are quite a number of low-growing plants that could be used which are too small for the ordinary greenhouse. A few names will indicate what I mean; there is, for example, Sedum cœruleum, Diascia Barberæ, Ionopsidium acaule, Leptosiphons, Meconopsis heterophylla, Hunnemannia fumarifolia, Nycteria capensis and N. selaginoides. Grown in shallow pans some of the above plants could with advantage be used in the alpine house. If I may be allowed to sum up the essentials for success, they are: (1) Thin sowing; (2) pricking off the seedlings before they become crowded; (3) cool conditions at all times for the hardy kinds, with free exposure to light and air; (4) careful watering at all stages of their cultivation; (5) timely staking or support to such as require it.

If properly grown on these lines there should be little or no trouble from insect pests, but if aphids should appear several light fumigations will soon destroy it.

J. COURTIS.

TO my first instalment of suggestions for your summer border of hardy annuals (THE GARDEN, December 31), which I hope you found it possible to read, incomplete as it was, you will have observed that the Editor, by way of instructive gloss, has supplied a charming illustration, with the legend, "An Annual Border in the Kitchen Garden." My own garden is largely a kitchen garden; but never in my life, kitchen garden or elsewhere, have I had such an admirably graded flower border as this, the truth being that my taste does not run in the direction of exact gradations from zero, from Ionopsidium, let us say, to Sunflowers of a giant stature. This, however, is a free country, or at least was—Government having, so far, not seen its way to inhibit or tax individual taste in flower arrangement—so that if you should perhaps favour the "grand stand" order of flower border, I would say by all means have it. The illustration gives you something in this way which is decidedly effective and which would not, I should think, be hard to achieve. For myself, I confess that, owing to some kink in my mechanism, the exact seat of which I have not been able to trace, any obtrusive regularity of arrangement always irks me, my notion of comfort in a garden being plenty of everything, and a "most admired disorder." And THE GARDEN artist himself, whoever he was, who created the flowery slope of the illustration in question, must have desired to avoid the excessive use of rule and plummet, otherwise why, half way along his border, does he introduce a flowerless shrub of some size, a Camellia or a Laurel, as it looks to me. Probably he

placed the shrub there to serve the double purpose of breaking the uniformity of surface and of watering down what might otherwise be an excess of colour; though possibly the shrub was there to start with, in which case it was a happy accident. Anyhow, I have a premonition that your border is going to err rather by excess than by defect of colour, and the question at present therefore is whether, having no Camellias, Laurels or other shrubs to fall back upon, you can find among hardy annuals any effectual means of correcting a too monotonous uniformity of surface or unrestful glare of colour. You certainly can find one or two things which will serve the purpose quite as effectively as evergreen shrubs. There is Kochia, for instance, which is hardy enough, provided you do not sow

too early. For a soft green, you can hardly better this annual, arranged preferably in groups of several plants. In autumn, to be sure, the green will change to red, but by that time many of your annuals will have gone off, and you may be glad of some accession of colour. The Kochia will grow to a height of 2ft. or 3ft.; but if you should desire something really tall and striking, with graceful and characteristic foliage, then sow a few seeds of Hemp (Cannabis indica). Should these prosper and reach a height of 5ft

SHIRLEY POPPIES AND LIMNANTHES DOUGLASII.

Unlike the many-faceted scheme outlined by "Somers," this border charms by its very simplicity.

or so, you will have your friends asking "What handsome tropical plant is that which you have repeated here and there in your border, and how, not having a greenhouse or even a frame, did you ever manage to raise such things?" But distinguished in appearance and useful as this plant is, I find it omitted from the lists of some important firms, possibly because of its ignoble association with ropes and their purposes. Then there are various annual grasses which you must not overlook, partly for their softening grace in the border, but especially because of their usefulness as a setting for cut flowers, such as Poppies and Sweet Peas. If you grow only one grass, let it be Hordeum jubatum—a graceful Barley with long awns of spun glass. You may also like to grow

the Quaking Grasses (*Briza*)—"Silver Shckels," as I have heard them called. I do not myself particularly care for these grasses, preferring, by way of "Shckels," those of *Bromus brizæformis*, which is of similar habit, but larger in the shckels and altogether handsomer than the *Briza*, though not perhaps so easy to grow. Also there are the Bent and Love Grasses (*Agrostis* and *Eragrostis*) and the Hare's-tail (*Lagurus*); though as a foil for cut flowers, speaking for myself, I find *Hordeum jubatum*, supplemented by grasses from the wayside, all that I require for the purpose.

I fear I have all this time been suggesting the means of correcting an excess of colour in your border, without having yet told you how to create the colour that is to be corrected; but that is a simple matter. Your border has a width, you say, of 10ft. If, therefore, we allow a space of 3ft. at the back for your Sweet Pea and Nasturtium hedge, with an additional foot of free space to enable you to pass along the border and gather your Sweet Peas, and, if, further, we assign 1ft. of border space behind the stone edging for planting, among the stones, the various annuals of dwarf growth formerly specified, that will leave exactly a breadth of 5ft. to be filled with those taller things which must give the border its body of colour. Most of the gayer annuals range in height from 1ft. to 3ft. Naturally, without desiring a regularity that will seem too artificial, you will still wish to have your flowers placed where you can best see them, which means that they must be planted more or less in *échelon*. In the 5ft., therefore, still left to be furnished with annuals, I will suppose two zones of height, the front zone to be filled with annuals of from 1ft. to 2ft. in height, the zone behind with plants ranging from 2ft. to 5ft. As a quintette of annuals for the front zone, I can think of no better combination than *Mignonette*, *Clarkia*, *Godetia*, *Candytuft* and *Nigella*. As much has been written about *Mignonette*, I should think, as about Shakespeare; so I will say nothing about the favourite annual except this—that it is a mistake to suppose the sole charm of *Mignonette* to lie in its perfume, for if you procure the right strains you may also have a most attractive display of brown-crimson and orange heads of bloom. *Clarkia* I have only late learned to appreciate at its true value. It has no great range of colour, but, within its range, you will not easily find whites and pinks which for softness and delicacy can beat the shades of the best *Clarkias*; while the outline of flower and spray is the last word in graceful beauty. I think, however, that the purveyors of *Clarkia* seed have been straining too much after double forms of the flower, which seem to me to lose in grace what they gain in substance. I cannot say that I am as partial to the *Godetia* as to the *Clarkia*. Nevertheless, I know few flowers better entitled than the *Godetia* to the epithet "showy," the superlative of praise so much in favour with gardeners. As I know the *Godetia*, it is a somewhat squat and stiff, and therefore sturdy, plant, with Mallow-like blooms (though it is not a *Malva*), set along the stems with little or no pedicel, which characteristic renders the spray less desirable for cutting. But the merits of the flower outbalance its faults. In the border it is a useful annual, holding itself well up, and furnishing abundance of vivid colour, from crimson through a gamut of rose, salmon and flesh to lustrous white. Not the least remarkable feature of the *Godetia* bloom is its surface texture, which has the lustre of a sheeny silk. You will do much to ensure the gaiety of your border if you make a plentiful use of *Godetias*. As for *Candytuft*, it is one of the gayest, hardest and most accommodating of annuals, so much

so that the wonder is it is not a common wayside weed. At any rate, it is a desirable garden weed. Sow it anywhere, and it will respond with a harvest of bloom, ranging through shades of white, lilac, mauve and crimson. I suppose white and the more intense crimsons are the favourite *Candytuft* shades, though for my part I prefer the more delicate and restful intermediate shades of lilac and mauve; and I also like the plants to be as dwarf as possible, the *Candytuft* at its tallest having a tendency to straggle and being then not particularly desirable as a cut flower. Of the *Nigella*, the well named *Love-in-a-Mist*, as of *Mignonette*, little need be said. We all value it—leaf, flower and seedpod. I know no annual that winters better than this. I have *Niggellas* in a small border which have come up unsolicited, year after year, for ten successive years. The white *Nigella*, as I know it, I cannot recommend. Have your *Niggellas* as blue as you can get them, and as tall. If you desire yellows in this front zone you cannot better Marigolds, not the French and African half-hardy *Tagetes*, but the genuine old thing that grew in the garden of "Mary, Mary, quite contrary"—the *Calendula*, if I must speak by the card. In these, if you get the right strains, you will have rich lemons and oranges, single or double; and very possibly some of your friends who have hitherto associated the flower with the kitchen (I believe there is a *Calendula officinalis* strictly so called) may wonder why they have never until now perceived the great beauty of the Marigold. If you associate with your officinal Marigolds a clump of the South African *Calendula pluvialis*, you will have a charming, black-eyed, white-petalled, purple-shaded Daisy, a barometer in its way, as sensitive to changes in the weather as an aneroid. Barometer flowers, be it noted in passing, such as the *Eschscholtzia* (which, however, is rather a biennial, or even a perennial, than an annual), *C. pluvialis*, *Anagallis* and *Convolvulus minor*, though so brilliant in full sunshine, close their petals in the shade and are therefore of little use as cut flowers. If, however, you love a soft, velvety, light-absorbing texture in flowers rather than the lustrous, reflected brilliancy of such flowers as the *Godetia*, you can have nothing that will better repay expenditure of your pains and pence than a patch of *Convolvulus minor* on some spot near the front of your border, where the full sunlight may reach it. Again, if you should wish to have well forward in this part of your border a composite of the first water, grow Sweet Sultans, well named "Sweet," for sweet they are, as well as pretty, and, in addition, exceptionally good keepers as cut flowers. When I see a jar of well grown Sultans, white, mauve and yellow, in a florist's window, I seem to find in them a high-bred distinction all their own, even in the near neighbourhood of such distinguished flowers as the Lily and the Rose. Besides those above noted there are other fine annuals of medium height, the bare mention of which is the only commendation I have space to give them—*Gypsophila elegans* (as fine as *paniculata*, if not finer), *Linum coccineum* (should you desire a good self crimson), *Dianthus Heddewigii* (very gorgeous when in good form), annual *Chrysanthemums* (tricolor and others), the dwarf *Nasturtiums* (which alone might furnish the front of your border), annual *Lupinus*, white, red, blue and yellow (some of them sweet scented), and the *Viscaria* (good for cutting).

The taller annuals required for the hinter-land zone of your border, if not so abundant as those of a dwarfer stature, are sufficiently numerous to allow a wide choice. If the space were mine I think I should fill it entirely with Cornflowers and Poppies. By "Cornflower" I mean the

Mazarine blue single Centaury that really does grow among the Corn, not the purple, mauve, pink and white forms into which the flower has sported in the hands of gardeners; though these sports, too, have a beauty of their own, and are not to be despised by those who like to see one species in many shades. If, however, you should wish to fill this part of your border with one splendid species in an infinity of pretty shades, try the Larkspur. It has not the stature and dignity of the Delphinium, nor, I think, has it that flower's absolute purity of blue; but it has points of advantage even over its perennial congener, in its finely cut foliage and its stocky candelabrum habit. Further, it has a wide range of colour, blue, purple, pink, mauve and white, and even scarlet, if you trust catalogue descriptions, though I cannot say that I have ever seen a scarlet Larkspur. A malvaceous plant for which you ought to find a place, if not in this zone, certainly somewhere in your border, is *Lavatera splendens*, to be had in a soft milky white and in two shades of pink. A lovely clean-looking Mallow is the *Lavatera*. Should you wish for a dash of yellow in this zone of your border, you might try *Coreopsis* of sorts, *Helichrysms*, *Rudbeckias* and *Sunflowers* of medium height. The *Sunflower* in its numerous varieties would furnish a border in itself, and associated with other flowers and in sufficient quantity it gives a mediæval touch to the garden not unacceptable in these "petrolie" times. To look at a *Sunflower*, you might think it had been contrived a million million years ago, while Nature was still an apprentice to her trade—it is so simple and primitive in its lines. But the *Sunflower* is not so simple as it looks. As a work of art, a flower, I suppose, ought to be judged by the ingenuity and effectiveness of its machinery for reproduction, and in this respect the *Sunflower* might give points even to the *Orchid*. By all means, therefore, have some of these pre-Adamite flowers in your border. Some of the taller sorts—yellow, primrose and brown-red—planted along the foot of your Sweet Pea and Nasturtium hedge would give the finishing touch of dignity to your border.

You requested me to advise you as to the planting of an empty border, possession of which you hold for only one season, with plants which must flower the first summer, and which require no glass or heat to bring them on. This I have done pretty fully, but I hope you will not credit me with the unwisdom of advising you to grow *all* the annuals I have specified or commended, or even a third part of them. You must make your choice according to your tastes and aspirations. There are two kinds of flower-gardeners in this island of ours, the æsthetic, and the curious or discursive, though, of course, there are some who are neither, but partly one and partly the other. If you have been stung by the æsthetic gaddy, as I rather think you have, you will grow your flowers in mass, and your attention will be given to elaborating schemes and combinations of colour. Should your harmonies "pan out" as you expect, you will be gratified, but not surprised; and, of course, you will be correspondingly disappointed when your well laid schemes "gang agley," as those of mice and men so often do. If you belong to the "massing" school, you had better procure from a reliable firm a few good things (*Clarkias*, *Larkspurs*, etc.) in assorted colours. If, on the other hand, you are a gardener of the curious and discursive school, as mainly I am myself, you will prefer to have not much of anything but a little of many things, and may conceivably be venturesome enough to attempt half the things in Thompson and Morgan's list. In that case you will also have your reward and your disappointments—failures many, but,

on the credit side, delightful surprises, harmonies also, unpremeditated, but none the worse for that, and opportunities numberless of gratifying an

insatiable curiosity; and after all, among human pleasures, how many are there that wear so well as gratified curiosity? SOMERS.

Mendelism Vindicated: A Visit to Primula-Land

Some of the best varieties of Chinese Primulas described, with the lines of present progress and cultural hints. A hardier plant than is often imagined.

GR^{EAT} improvements have of late years been effected in the colour range and general character of the Chinese Primula (*P. sinensis*). This was made very apparent on a recent visit to Messrs. Sutton's trial grounds near Reading. Very remarkable indeed was the trueness to type of the as yet unrogued batches of the varieties already in commerce or to be placed on the market this season. Among these only one rogue was

All the popular giant forms show a generic similarity. The green-stemmed Giant White has a pretty soft pink counterpart in Giant Pink. For those who prefer dark-stemmed plants Giant Royal White is provided. This is equally as vigorous and beautiful as the green-stemmed form. Giant Scarlet is of bright and pleasing shade of colour, though it is a long way from scarlet in hue. It is scarcely necessary to say that there is no true scarlet Chinese Primula in

generally useful is probably Reading Pink. Shades of pink are always difficult to describe, and with the Primula the difficulty is increased by a little difference between flowers in varying stages of development and also a difference of tint noticeable with the varying season of the year. Suffice it, then, to say that Reading Pink is of a very pleasing shade of colour. It has, too, the additional merit of being very free-flowering, as the original centre spike is followed by numerous side spikes of almost equal size and vigour.

Of the so-called "blue" flowered forms, the three now cultivated in this section are Reading Blue, of a pale lilac tint, but quite pleasing, especially in association with Sutton's Coral Pink. The Czar is a bluish purple shade, not ineffective; indeed, by many much admired. Oxford Blue is an intermediate shade.

Etna will be familiar to many readers as the glowing crimson dark-foliaged variety which proved so effective at the shows last season. Of the white, pink-centred Duchess there is little need to speak, since a similar coloured strain under that name has been in commerce for close on twenty years. "Her grace" dates back to the days before Mendel's discoveries had been practically applied. It is interesting to note, none the less, that this form is the typical recessive found in the second generation (F₂) when a crimson form is crossed with a dark-stemmed white one.

To those interested in heredity the origin of the coral pink form is interesting. This was a true sport found in a batch of the then existing strain of Crimson King. It proved to be definitely and permanently fixed to type. There is, a little consideration will show, a well marked tendency for colour forms lying between crimson and blue to throw, especially under cultivation, sports of some clear shade of pink. Plants which readily come to mind in which this has occurred include *Primulas japonica* and *pulverulenta*, *Centaurea montana*—the form is called Lady Florence Hastings—and *Linaria alpina*. Almost all the wild species of Orchis of a purplish hue to be found in our meadows can also be found occasionally of a beautiful clear pink colour. The explanation would seem to lie in the fact that in some way a colour-bearing factor is dropped. With this factor it is evident that some of the plant's hardiness and vigour is but too apt to depart also. Sutton's Coral Pink *fimbriata* shows to some extent this tendency, inasmuch as it is somewhat less vigorous than the other colours. The beautiful coral pink *stellata* form of which we presently shall speak is, however, commendably robust, but then vigour is characteristic of all the Star Primulas.

Before considering these so-called Star forms—though they are now noticeably getting less starry—let us turn aside to look at a large batch of the double-flowered Queen of Pinks. Double-flowered Primulas there have been for a long time, and very useful they are to the florist, especially the white form, as the flowers when cut are very lasting. For greenhouse decoration, however, they are not so satisfactory owing to their unfortunate habit of hiding their blossom among the foliage. But a small percentage, too, usually comes true from seed. Queen of Pinks is of vigorous habit, the foliage is arranged to form an all but perfect rosette, and the flowers, which are rose-shaped, wonderfully double and even in appearance are borne well above the foliage. The beautiful colour of the blossoms, the large trusses and the fact that it reproduces itself quite true from seed all combine with the good points already enumerated to make this a very notable addition.

Of the older Star forms of *Primula sinensis* there is no need to speak; their value for decorative purposes is so well understood and so widely admitted. A novelty of which Messrs Sutton

THE SNOW-WHITE ("EYE-LESS") PRIMULA SINENSIS SILVER STAR.

noticed, namely, a delicate pink form in Sutton's Giant Royal White. This plant had the characteristic habit and dark stems of the type, and it was the only one distinctly untrue among several hundred plants of the variety.

Nor were the varieties in commerce or about to be placed on the market the only ones true to type. Many absolutely fixed stocks which cannot be in commerce for some few years were to be seen. The immense pains which are taken to improve strains by the famous Reading house may be illustrated by the variety Crimson King. The original Crimson King, though highly esteemed in its day, is a dowdy purplish shade compared to the Improved Crimson King which replaced it, but even this has a very "washed-out" appearance compared to the fine form now supplied under that name. There is, however, no such thing as finality. Already a strain, which records an improvement alike in colour and substance, is being worked up to replace the form already on the market. This is not an isolated instance: it typifies the care which is taken to select and reselect, so that the stocks sent out may be as nearly perfect as possible.

commerce, although—but of that anon. The peculiar value of Giant Scarlet lies in the fact that it is naturally the earliest of all to flower. From seeds sown in April plants may easily be had to blossom in November, or even, with a little management, in October.

There are several large-flowered "blue" forms, but so far no giant "blue" flowered strain in existence, or, at any rate, known at Reading. Messrs. Sutton have this season a plant of The Czar, which truly represents the giant-flowered form, but they are pessimistic as to the chances of perpetuating it. A similar break has occurred before, but they have always failed to harvest seed. It may be mentioned that all strains of *Primula sinensis* may readily be fixed with either palm or fern leaves, but the old palm-leaved type is a long way the more popular.

The older but very useful large-flowered *fimbriata* forms years ago superseded the original entire-edged form typical of the wild species, only themselves in a later day to be partially superseded by the more robust habited but entire-edged forms now called *stellata*. Of these large-flowered *fimbriata* forms the most

think highly is Symmetry, which will shortly be placed in commerce. Wonderfully vigorous and free, the flowers are much larger and more symmetrically formed than with the older stellatas. The colour is a shade of carmine rose, and to those who love pure bright colour this is its weakest point.

The writer found it easier to enthuse over the Improved Giant White Star. The flowers of this variety are even larger and more substantial than in the case of Symmetry, and they are freely produced and admirably carried. Sutton's Dark Blue Star is not really very deep in colour. It is, indeed, just of a shade to form an admirable foil for the truly beautiful Coral Pink Star which is probably to-day the most popular of greenhouse Primulas.

Messrs. Sutton have now turned their attention to a Star-flowered strain with a tiny white eye instead of the yellow one so characteristic of these Primulas. Typical of these is the rosy crimson Enchantress, which flowers quite as profusely as the older Star forms, and is very distinct and effective. Most extraordinary and fascinating, however—at least the writer found it so—is a pure white one which, having a white eye, becomes a real self-coloured form. The plant has dark foliage, and the freely produced spikes with two or more whorls of flowers are singularly un-Primula like. Messrs. Sutton compare the flowers to those of Primula "nivalis," but the tendency to "cup" so noticeable in P. "nivalis" is absent. The whole get-up of the spike (disregarding, of course, the foliage) reminds one forcibly of the White Champion (*Lychuis vespertina*). This variety, which is called Silver Star, should, once the public gets used to its unconventionality, become very popular for conservatory and room decoration.

Turning now to the breeding at present being carried on to provide new varieties in the not distant future, one of the first thoughts that strike one is the difficulty of selecting from the many forms raised the ones which the public will endorse. Some of the beautiful forms raised cannot, unfortunately, be fixed. Before any attempt is made to do this, however, many interesting types must of necessity be rejected. There are, for instance, what may be called The Sirdar forms. Sirdar is a mauve variety raised many years ago with a "wire" edge of white which gives it an appearance comparable to the old laced forms of Polyanthus. Judging from seedlings on view in the second generation of a Sirdar cross, there would appear to be no difficulty in reproducing this lacing in almost every colour. With the lacing goes a certain bizarre appearance of the whole truss created by variations in flower colour. The blossoms in this strain often open quite pale, but rapidly strengthen in colour. The question here is, do the public want such a strain?

Mendel's Law has been of inestimable service in systematising the raising of new Primulas. Before its principles were introduced an immense amount of labour was wasted because reliance was placed only on the first cross, which is, in fact, normally unfixable, and no effort was made to "self" the plants resulting from this cross and so allow to come forth the immense diversity of forms which is almost always, under such circumstances, produced. This notwithstanding, the Chinese Primula, though it usually follows fairly well the expected course, occasionally behaves in an inexplicable way. A certain cross now to be seen under trial has results very difficult of explanation. The names of the varieties are immaterial, but the facts are as follows: F₁ showed, surprisingly enough, little or no variation from the seed parent, although there appeared no reasonable doubt that the cross had taken. The plants were self-pollinated, and F₂ was raised

in the usual way. It was naturally expected that either (1) the original cross would prove not to have been effected, in which case the plants would reproduce the original seed parent, or (2) the seedlings would show a very considerable diversity alike in habit and colour of stem and flower. The fact is that the whole batch of plants are exactly similar in habit and colour of stem, and as far as one can see—they have not all flowered yet—precisely similar in blossom colour. They have, in fact, the exact appearance which one would have expected to find with the original cross the previous year. All natural phenomena are susceptible of explanation. There is room for the best brains to study this conundrum.

Messrs. Sutton have endeavoured to cross the golden yellow hybrid Primula kewensis (floribunda × verticillata) with a sinensis form. The resulting plants are yellow flowered and mealy—this is not uncommon with P. kewensis, though not a constant trait, but they assuredly have an unusual appearance, a little reminiscent, perhaps, of P. verticillata. One wonders has the cross, in fact, taken, or has the alien pollen merely served as a kind of catalytic agent to release some latent factor in the seed parent?

Plant breeding is a source of never-failing

interest, but space will not permit to discuss at greater length the results Messrs. Sutton are achieving, further than to say that if two types already raised prove fertile and fixable, the day is not distant when a true scarlet and an equally pure crimson (devoid of blue) will be added to the many attractive colours already in existence.

There is a fairly general misconception as to the hardiness of the Chinese Primula. The cooler the conditions under which they are grown so that frost be excluded the better. The only possible exception to this rule is fimbriata Coral Pink, which appreciates a few degrees more warmth, especially if overhead heating is provided. It should not, however, be coddled. Messrs. Sutton's main sowing is made about the middle of June, and the young plants remain in cold frames, with the lights off, until October. The frames are in full sun, and it must be very exceptional weather if any shade is afforded. The treatment given accounts, of course, for the robust, close and stocky growth upon which all visitors to the trial ground comment. In the south-west and elsewhere where hard frost is not experienced there is no reason whatever why these beautiful flowers should not be grown and flowered successfully in an unheated greenhouse.

SOW SNAPDRAGON SEEDS SOON

Anyone can grow Antirrhinums. With a little trouble anyone can grow them well. Alas! few do.

THESE are more in raising seedlings than dropping seeds in the soil. True, Antirrhinums are among the plants of simple requirements, and may be raised from seed with very little real difficulty, but the summer's display of bloom is largely dependent upon the proper observance of a few points in regard to the management of the tiny seedlings, and as it is now time to sow seeds for the production of plants to bloom from July to October, we may profitably meditate upon these few points.

It may be considered superfluous to say that the first essential is to procure seed of the highest possible quality, but the fact that there is, every season, enough sale of cheap, nondescript seed to encourage the vendors to continue their business in the same groove can only be interpreted as evidence that not everyone realises that only the best should be good enough to bother with, and there are few plants which show a more marked difference between the best and the "rest" than is shown in the seed stocks of Antirrhinums.

The soil in which the seeds are to be sown may very easily affect the whole career of the plant. Many people make a practice of sowing all seeds in sifted leaf mould alone. That is not conducive to success with Antirrhinums. The seedlings grow too rapidly and too soft at the outset, and soft, sappy growth at any stage in the development of an Antirrhinum plant is not conducive to the best results. It may be argued that any detriment may be avoided by using a soil of heavier texture when the pricking out stage is reached; but no, that will not do, for the roots that have started in a soft, light leafsoil will take longer to get hold of the heavier soil, and thus the seedling suffers a check. The best soil is a fibrous loam, into which a fairly liberal quantity of sharp sand is incorporated. The boxes should be shallow, not more than zins. deep, for if a greater depth of soil lies beneath the seed the roots go ramping through the whole body, and as they travel downward the tops become elongated with lengthy spaces between the joints.

What is wanted is a stiff, hard, short-jointed growth.

The seed should be sown thinly. It is far better to sow two boxes than to overcrowd one. Do not sow deeper below the surface than is necessary to hide the seed from view. The covering of fine soil should only be as thick as the seed itself. Do not pat and press the soil over the seed. Watering with a fine-rosed can will do all the settling required.

Antirrhinum seed requires but little heat. A temperature of 50° to 55° is better than one over 60°, and as soon as the seedlings show green through the soil, place the boxes on a shelf near the glass, where they will get the benefit of free circulation of air and plenty of light rather than the heat from closely adjacent hot-water pipes.

Do not let the seedlings get really dry or they will wither very quickly, but on the other hand carefully avoid over-watering as sodden soil will cause damping off.

As soon as four leaves are formed the seedlings should be pricked off, and in performing this task firm the soil at the roots. Loose soil is not good for Antirrhinums even in the earliest stages of growth.

For a few days after pricking out it is well to keep the plants in a close, but not overheated, atmosphere in order that there may be no loss of vitality through evaporation of moisture through the leaves. As soon as root action has restarted, ventilation should be given, cautiously for a day or two, and thenceforward freely, except when frosty winds prevail. The cooler the young plants are kept the sturdier and healthier they will be.

By the time the plants get to a height of zins, the points of the shoots should be pinched out, unless the aim is to grow one big spike of bloom to a plant, in which case the plants should be potted, kept near the glass, removing the lights entirely during the middle part of favourable days. When side shoots appear they should be pinched out to encourage concentration of strength in the central stem. These single-stemmed plants must not be allowed to become pot-bound before planting

out, but when planting is done the soil must be firmly trodden round the ball of roots.

The plants that are "pinched" will soon throw out side shoots, and if one aims at the highest possible success, the young plants should be potted off singly as soon as the side shoots have formed a couple of pairs of leaves. The advantage of the potting is that the plants will continue to make

steady progress, and will receive no check when eventually planted out. I have had plants treated in this way that have commenced to bloom before they have completed five months from seed sowing, and from the same plants I have had thirteen weeks' unbroken succession of bloom, a result that surely well repays the moderate demands made upon one's time.

A. J. MACSELF.

CORRESPONDENCE

A NATIONAL DAFFODIL SOCIETY.

WILL ITS SUPPORTERS PLEASE READ THIS?

I AM now in a position to say that the Royal Horticultural Society have most kindly placed a Lecture Room at the disposal of those who wish to talk over the formation of a National Daffodil Society on Wednesday afternoon, March 15. I accordingly ask all those who are interested in the proposal to note the date and try to make a point of attending. I think two o'clock would be

one and all look at it simply and naturally, without prejudice or other distracting thoughts! The real effort should be to encourage and so rope in year by year more and more members. It therefore seems self evident that unless those future supporters are brought into direct touch with the flower in question, no hope of real and steady advance can be expected. The most successful, that is, most widely successful, shows in the world are those that have a broad policy. In conclusion, bring the shows to the people! and bury once and for all

ONE OF THE MOST BEAUTIFUL OF PRIMULAS FOR THE ROCK GARDEN—PRIMULA × PUBESCENS ALBA, COMMONLY KNOWN IN GARDENS AS P. NIVALIS

the best time for the meeting to begin, as there are several schemes in the air which will need careful consideration. I hope the time and date will be found generally convenient. No objection to a meeting, as I suggested some time back on the second day of the Forced Bulb Show, has reached me. There is none down this year on the R.H.S. List of Fixtures; had there been one, however, this would very likely have been the date. As far as one can gather, opinion seems to be setting in three main directions: first, to leave things more or less as they are; second, to form a National, or it might be, better still, a British Daffodil Society, either incorporating or not incorporating the present Midland Society; and third, to establish a sort of Octopean Association of British Bulb Growers which, in addition to watching the interests of big and little growers of bulbs, would also hold shows and put out literature.—JOSEPH JACOB.

FROM the present controversy in your columns the formation of a National Daffodil Society would seem to an interested outsider at first sight to be a difficult and complex problem. But let us

the self-centred policy of some people.—AN OUTSIDER.

MR. ENGLEHEART appears to be in a minority of one, so I trust that he will not become a "Die-hard," but acquiesce, with a good grace, in the wishes of the majority.—BRODIE OF BRODIE.

"REQUIESCANT."

WOULD the gentle "Somers," "Rummager of the sylvan haunts," have us consign our Daffodils for ever to mead and moor, to waste their sweetness on the stilly glade, denying them the homage they receive at Vincent Square and other places, from us their worshippers, with our infernal din, irrational zeal and damnèd iteration? I like not "Somers'" phrases, Mr. Editor, and as for his—I was going to call it metre!—I shudder to think of the expression that would come into the serene poetic eye of immortal Horace, were he by some mischance to see the first part of column 1, page 9, Vol. LXXXVI of THE GARDEN. Let us fervently agree "Requiescant."—W. A. WATTS.

[Our correspondent seems not to have noticed the letter of Rev. G. H. Engleheart in our issue of

December 24. Poor "Somers," after all, only set another's sentiments to tune. Despite Mr. Watts' caustic criticism we think it unlikely that Horace would single out "Somers'" verses for especial detestation.—ED.]

WHAT IS THE ORIGIN OF PRIMULA NIVALIS (OF GARDENS)?

I CONSIDER this grand old plant one of the loveliest treasures that one can possibly have in the rock garden. It must be a very, very old garden plant; it is not really difficult to grow, and yet for some reason it is extremely scarce. Really, of course, it should not be called *nivalis*. The true *nivalis* is one of a group of extremely difficult, and therefore very rare, *Primulas*, most of which come from the East. In the *nivalis* group are such lovely things as *P. Farreri*, *P. chionantha* and *P. sino-purpurea*.

But the old *P. nivalis* of gardens belongs, of course, to the *hirsuta* fraternity. It has the woody stock of *P. hirsuta*, the same leaves, and a full round head of white *hirsuta* flowers, with all their delicious *Auricula* fragrance. Roughly, it is like a glorified albino *Primula hirsuta*. But what really is the plant, and when and where did it originate? Is it an albino form of *hirsuta*, collected wild; and, if so, who collected it, when and where? Or is it a chance garden seedling, or a hybrid? Who can say? I wish one of our careful plant historians, Mr. Brotherston, say, or Mr. Ingwersen, would investigate the matter and give us his conclusions. I have seen in certain Scottish gardens a plant which, except in colour, is almost identical with *nivalis*—the same leaf and habit, the same full rounded head, but the flowers are lilac or pinkish mauve. One might almost be a sport or a seedling from the other.

Whatever the origin of "*nivalis*," there can be little doubt that the whole stock has originated by division from our original plant. It is not a race of seedlings. There is never the slightest variation among the plants. The flowers are always "pin-eyed." What happens if you self-fertilise flowers of *nivalis* and sow the resulting seed? The answer in my case is disaster. I "selfed" several heads of *nivalis* flowers last year with the greatest care, obtained sound-looking seed, sowed it, and then some bright soul knocked the pan over, scattered all, scooped it up and stuffed it back, so that nothing happened—not even to the bright soul. I have asked two careful plantmen about "*nivalis*" seedlings, one of whom tells me that from "selfed" seed he got nothing but true white *nivalis* seedlings, while the other got coloured seedlings of all shades and no whites at all. So there you are! Meanwhile the old *Primula nivalis*—of gardens—which might perhaps be better called *P. hirsuta nivea*, being snow white, rather than snow haunting—continues one of the most charming of rock garden plants.

In the matter of culture it enjoys a cool position and a cool rich soil, rich especially in the sort of humus that retains moisture—stiffish loam with a good deal of leaf-mould and cow dung. Lastly, do not always be dividing it and chopping it up. It likes to spread quietly and steadily. It likes to get its leaf tufts off the ground, and it develops a leg for the purpose. It hates being continually messed about.—CLARENCE ELLIOTT, *Stevenage*.

[Mr. Elliott has raised a very interesting question. It was indeed a sad misfortune that his laboriously produced seed was lost. If, as Mr. Elliott thinks, however, the seed was fertile, what are his grounds for supposing that all the plants in commerce have been increased vegetatively from one? The pin-eye in *Primulas* (in *sinensis*, at any rate) is

recessive, so that one would expect the selfed progeny to be pin-eyed also many white forms breed true. We shall be glad to publish anything which will throw light on this very interesting and beautiful little plant.—ED.]

AN INTERNATIONAL DAISY SOCIETY?

THE arena of the much discussed "National Daffodil Society" is ground on which, I confess, I fear to tread; it is already crowded. Still, I have my own personal reasons for putting in my oar and bringing Mr. Engleheart to book on one point of his recent letter. Athenasius *contra mundum* is, I am well aware, abundantly able to take care of himself. Mr. Engleheart, however, must not suppose that he is always right. I have had, before now, occasion to question propositions which he has advanced with some seeming authority; though I am prepared to admit that even when I find him in error, Mr. Engleheart puts his errors in such cogent and convincing form that they are almost as persuasive as syllogisms. It is therefore with some hesitation that I take exception to his statement that the Daffodil does not sufficiently appeal to the populace, not so much as the Sweet Pea, he thinks, or the Rose. I do not know about that. For my part, I measure the popularity of a flower by the number of persons it brings more or less into the limelight. Why is there no "Royal Orchid Society"? "Because," Mr. Engleheart would answer, "Only Dives can possess Orchids. The purchase of one Orchid between them would leave Tom, Dick and Harry bankrupt." A poor argument, surely. I do not know about Tom, Dick and Harry; but look at the number of patrons, presidents, vice-presidents, chairmen of committees, members of committees and sub-committees, treasurers and vice-treasurers, secretaries, sub-secretaries and assistants to sub-secretaries, editors, sub-editors, auditors and the like, whose names it would be possible to put on the prospectus of such a society and in the annual reports, gratifying, in this simple way, for so many, a harmless ambition. I know of one Daffodil Society already in existence which pursues the modest tenor of its way from year to year, and which, without arrogating to itself the name of "National," brings up to the footlights many persons who, without its help, might have been left to "blush unseen"—namely, one president, eighteen vice-presidents, one hon. treasurer, one hon. secretary, one chairman of committees, seventeen members of committee, and twelve members of sub-committee.

I admit that in challenging this one point in a case otherwise convincingly put by Mr. Engleheart, I have my own ulterior motive; the fact being that I have in my mind's eye, a society which, I suggest, should be termed "National" or, perhaps, bettering the suggestion of distinguished Narcissists, "International." It seems to me high time that we had an "International Daisy Society." When, therefore, this Daffodil storm subsides, I may possibly find it advisable to call a meeting of other distinguished Daisivists with the view of establishing an "International Daisy Society," under the patronage of the President of the United States and the Crowned Heads of Europe—with, I need hardly say, myself as Founder, and a full complement of officials, sub-officials and sub-sub-officials, the number of the said officials (whatever powerful arguments may be advanced to the contrary) to be strictly limited to 120. It I have my way—as, of course, being founder, I shall have—the I.D.S. will have its home at the most central spot available, say, Edgbaston.—SOMERS.

"SOMERS" has bettered the Rev. J. Jacob's suggestion (in last week's issue) of further nuts

for the coffin of Mistress Daffodil: he has planted the Daisies but—is she buried?—ED.]

A PRUNING QUERY.

I HAVE been interested in the articles on Pruning by your correspondents, Messrs. O. Thomas and Pearson. I have just planted a maiden fan-trained Apricot tree, having one shoot about 2ft. long on one side, two shoots about the same length on the other side, and a strong leader, say, 3½ft. long. What would be the difference in the pruning of this tree by the two gentlemen mentioned. I thought to head back the leader to half the length and reduce the three side branches by about a third of the length. I should much like to hear the opinions of Messrs. O. Thomas and Pearson on the subject, or if too small a matter for their notice, perhaps the Editor would pass his criticism. Trusting I have not encroached too much on your space.—F. W. HARRIS.

THE SEED OF A FLOWER.

Alone, unlovely, on the dark earth lying,
Naught in its form to stay the passing eye,
Rests a poor relic of a flower's past glory
Seemingly cast aside and left to die.

Yet in this shell a germ of life lies sleeping—
Promise of living beauty yet to be
And sum of all that passing years have gathered—
At once a record and a prophecy.

A glowing ember, from the sacred fire
Of one of Nature's floral altars taken,
Concealed within this humble form, has come
An answering fire in this far land to waken.

For on the slopes of some great Eastern mountain,
High o'er the plains where burns a tropic sun
The flower which bore it dwelt for generations
And there its course, long undisturbed, did run.

Till, Siren-like, it lured at last to slumber
One dauntless heart, now living but in name;
For the wild land that held the flower in beauty
Now holds the man who for that beauty came.

He passed through toil and hardship ere he found it,
Stayed until all its outward charms had flown,
Then saved the seed in which they now are lying
Unseen and still, to many an eye, unknown.

But when at length the genial warmth of heaven
And rain and air of earth their part shall play,
This morning star of life in darkness shining
Will pass into the splendour of the day.

A. E. SIMS.

A GRAND ANNUAL CLIMBER.

IN THE GARDEN of December 31 a writer recommends four climbing annuals to be used for covering twiggy stakes in the background of a border, namely, Sweet Peas, climbing Nasturtiums, Canary Creeper and Japanese Hop, and says he can think of no others. Now last spring (in April) I sowed the first two in the same way, alternated with Convolvulus major, and the Convolvulus was far and away the most successful of the three. The Sweet Peas in this particular position (at the back of a border of mixed annuals) flowered early and made poor growth, owing to lack of special preparation of the soil, the dry season and some unavoidable neglect. The Nasturtiums did not take kindly to the Hazel and Willow twigs with which I provided them. Being climbers of heavy growth they require solid support. They flourished a few yards away among old overgrown Rose bushes and on a Virginian Creeper-covered east wall, but they had little confidence

in the light temporary hedge and preferred to run along the ground. The Convolvulus, however, made up for the deficiencies of the other two climbers. I sowed three seeds to a clump. (They were afterwards joined to form a light hedge with extra stakes and twine.) The whole lot came from one 2d. packet of mixed seed. They made tremendous growth, were in flower when I returned from Italy in July, and lasted till the frost in November. The colours included a clear rose, blue, blue with crimson rays, white with bluish grey rays, pure white, and the most ethereal and delicate pale blues and pinks. They would, of course, be useless for an evening garden, as every flower is closed for good by 6 p.m.; but, considering that each flower lasts only for a day, the number of blooms appearing at one time is perfectly astonishing. I have seen the plants simply covered with flower day after day. The only time when they fail is in windy weather. The flowers are so delicate and easily torn that even a light breeze in the morning will destroy the flowers of the day, so that they would not be suitable for a draughty position. A curious fact may be noted. The blue flowers must be admired in good time in the morning. After eleven o'clock or thereabouts (varying a little according to the sunniness of the day) the blue takes a purplish tinge, and by three in the afternoon all the flowers which are not white are pink. There is not a blue one to be found. The same thing happens when a spray has been gathered and put in water and the flowers have opened in the house. It was probably owing to the hot, dry summer that Convolvulus major did so particularly well in East Yorkshire last year, but it is an old-fashioned flower which is well worth growing in a sunny and sheltered position.—RUTH BICKERSTETH, *Hyères*.

BUSY NATURE.

I NO longer wonder that Mr. Kettle's Lloyd George Raspberry and many other good things have been found as chance seedlings, when I have an object lesson of how Nature distributes seeds in my own garden. It is so striking that it may be of general interest. In the summer of 1916 one of my small greenhouses had either to be scrapped or re-erected. I chose the latter alternative. When the work was finished there was a narrow long space between two houses (3ft. by 20ft.). No wild vegetation of any kind appeared until 1917, as it was up till then filled with bulbs in pans and boxes, and kept clean. Since that time it has remained absolutely untouched. Last year (1921) I ate a ripe Strawberry (not a wild wood Strawberry by any means) and a ripe Raspberry gathered from self-sown seedlings in this narrow space. There is also a small Gooseberry bush and a Loganberry, which, however, up to the present have not flowered; several Birch trees, one now 8ft. high; a Salix of some kind, and, of course, a fair number of ordinary weeds. The Birches do not surprise me. There are four large trees in the garden and every year the seedlings are so numerous they are a perfect nuisance; the Loganberry does not surprise me, but where did the Strawberry, the Raspberry and the Gooseberry come from? I have had no Strawberries, Raspberries (except Hailshamberrys), or Gooseberries in the garden for at least twenty years. The nearest Raspberry canes are 200yds. off, and the nearest Strawberry plants quite a quarter of a mile. There are some Gooseberry bushes within 50yds., and I have about a dozen Loganberries. I can only imagine that birds were the distributing agency, as is so often the case; but that seeds of these three fruits should have so soon been dropped in such a small space is very striking. Other experiences would be interesting.—JOSEPH JACOB.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Asparagus.—Should new beds be contemplated, it would be best to have them prepared beforehand, not only to allow a settling down, but because when planting-time comes in early April there is such a pressure of important work to be dealt with that nothing which can be done now to expedite operations then should be left over. The beds should be thoroughly well made by deep digging and working in plenty of manure. It is essential that Asparagus has a well drained rooting medium, and to assist in arriving at this end the beds must be raised several inches above the level, and on heavy land a foot is advisable.

Cauliflowers.—Plants which were pricked out into frames during the autumn will be in better condition for planting out a little later if they are now lifted and placed in suitable sized pots. After potting, keep the frames closed for a while to enable the plants to pick up quickly, afterwards admitting plenty of air when weather conditions are favourable.

Cabbage Plot.—Any blanks in this plot should be filled up with plants from the autumn reserve seed-bed, at the same time making firm any plants loosened by the frequent strong winds. If the ground is workable, a light hoeing will be beneficial. Should there be any doubt about sufficient stock, sow some seed at once and germinate in a newly started fruit house. Prick out as soon as possible and keep the plants sturdy. By the end of March or early April these will be good plants, ready for putting out, and will come along very quickly afterwards.

Seakale.—Any further roots intended for forcing and which are still in the ground should now be lifted, thonged and stored in sand or soil in a cool place.

The Flower Garden.

Propagation.—This must now be rushed along where large supplies have to be dealt with. Where Lobelias, Coleus, etc., are still used for edging or groundwork a mild hotbed will be found the best way to quickly get any quantity rooted. Only a little depth of soil is required in the boxes, etc., and let this be light and sandy. Autumn-struck batches of different plants must be potted or boxed now and kept growing quickly in a suitable temperature.

Plants in Frames, such as Pentstemons, Calceolarias and Antirrhinums, should be occasionally examined and the soil stirred to sweeten it. On mild days an abundance of air should be given so that strong plants will be built up ready for removal to their permanent quarters.

Seeds of fibrous Begonias, Pentstemons, Verbenas, Antirrhinums, etc., of which the seedlings take some time to come to maturity, should be sown now, placing the former when sown in the warmest position. The sowing of seeds will now call for continual thought, and must be dealt with to suit the varying needs of the different places. By following the advice printed on seed packets from nearly all firms of repute even the beginner cannot go far astray, unless it be in sowing seeds too thickly sometimes and covering fine seeds too heavily.

The Hardy Fruit Garden.

Small Fruits of the rambling class, such as the Loganberry, Wineberry and the Parsley-leaved Bramble, not having yet received the necessary pruning should be seen to as soon as possible. The chief need is the removal of old wood and weakly shoots and the tipping of all weak ends of those shoots which are retained for this season's fruiting. If so desired, the planting of any of these bushes can be carried out right through the present month when weather conditions permit. See that all supports may be relied upon to carry through the season.

American Blight.—Trees badly infested with this pest should first of all be gone over with a fairly stiff brush and one of the insecticides advertised for its destruction. Afterwards a good syringing should be given, taking care that a thorough wetting is given to all parts of the trees affected. When it is known that a tree is also badly affected below ground with this pest an injection into the soil, when it is dry, of carbon bisulphide, keeping several feet away from the trunk, will probably kill it. The liquid must be kept from the roots. A couple of ounces should be sufficient unless on a very large tree; the injections of the soil should be given in several places. Quite a good syringing wash is a mixture

of soft soapy water with a wineglassful of paraffin added to every three gallons. Some also add quassia wash.

Fruit Under Glass.

Early Vines, whether growing in pots or borders, will require a little more heat as the buds swell and break. A night temperature of about 58° to 60° will suit, with a corresponding day rise. As the days lengthen and activity is more pronounced the atmosphere may be kept a little more humid, but this must not be excessive or soft, flabby leafage will be the result, especially if high temperatures are maintained. As soon as it can be determined which buds will be retained all the others should be rubbed off to avoid loss of energy. Particular care should be taken to see that Vines in pots do not suffer from root dryness. When watering is done let the whole ball of soil be well moistened through.

H. TURNER,

(Gardener to the Duke of Northumberland)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Parsley.—Make a sowing of Parsley seed in a box or seed-pan and place in a moderately warm house or hotbed. In this way fine plants may be had ready for planting out in the open border immediately danger of severe frost is past. A colony may also be planted in a frame for earlier use. When sowing, choose a close-growing strain—Austin's West of Scotland Prize is very fine and can be justly commended either for competitive or ordinary purposes.

Cabbages.—Run the cultivator between the rows of the autumn-planted batch and make up any blanks from the reserve bed, at the same time making firm any that may have become loosened at the neck through the action of the wind. Sow seed of Sutton's April and Harbinger in boxes for pricking out into frames as a successional crop.

Peas.—A sowing should be made in boxes at this time for planting out in the open later on. Narrow boxes, about 4ft. long by 4 ins. wide and 5 ins. in depth, are admirable for this purpose. Place a thin layer of rough material in the bottom and then use a mixture of ordinary potting soil. Place the seeds about 2 ins. apart when sowing and press the soil firmly when finished. Germinate in an ordinary greenhouse temperature, afterwards transferring to a cold frame when the seedlings are about 1 in. high. We find Pilot and William the First Improved the hardest and most reliable varieties for our first crop.

Fruit Under Glass.

Vine Eyes.—Where it is desirable to raise young stock, now is the time to insert the eyes. Choose eyes from sound, thoroughly ripened wood, the most satisfactory being those generally found at the base of the laterals. The eye should be cut with about half an inch of wood on either side of the bud. Many growers root the eyes in turves, but small pots are best as less root-disturbance occurs when the time arrives for transferring to larger pots. Use a light loamy compost with some sharp sand added, and fill the pots up to within 1 in. of their rims. Place the eye on this and then cover over, leaving nothing but the bud showing on the surface. Plunge the pots in a propagating case in a house where a high temperature is being maintained.

The Hardy Fruit Garden.

Spraying of Fruit Trees.—Work among the hardy fruit trees should be sufficiently advanced to allow the work of spraying to be carried out before any appreciable swelling of the buds takes place. Calm weather is essential for spraying, as when a breeze springs up the spray can never be properly directed to all parts of the tree, and hence is wasted.

Planting Fruit Trees.—Where circumstances may have hindered the planting of bush fruits or trees during November the work may be successfully carried out during the present month. On the arrival of the trees from a nursery they should be planted immediately, provided the weather is suitable. Should bad conditions prevail, however, heel the plants into temporary quarters, taking care that the roots are never exposed to the air for any length of time or allowed to become dry.

The Flower Garden.

Lobelia.—Seed of this indispensable edging plant should be sown now, as owing to the excellence

and compact habit of the many varieties that selection can be made from, the necessity of raising Lobelia from cuttings has in a large measure ceased to exist. The variety Mrs. Clibran is very compact and the colouring is very attractive and irregular. Sow in well-drained seed-pans, using a light compost with a sprinkling of silver sand on the surface. Do not cover the seed, simply press the surface with a smooth board, cover the seed-pan with a piece of glass and place in brisk heat, shading from sunshine until germination takes place.

Pæony Moutan.—Examine the various plants of these and cut out any weak shoots; also cut away any dead points from last year's growths, cutting right back to the first strong bud. Many of the grafted Tree Pæonies are inclined to throw suckers; these should be removed directly they are observed. Give a generous mulch of well-rotted manure, afterwards dressing over with old potting soil.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Lachenalias that up to now have been growing in cold frames may, as the inflorescences begin to show, with advantage be removed to a light and airy greenhouse. Like so many South African bulbous plants, their growing season is during our winter; it is therefore of prime importance that they should have as light a position as possible during the dull weather conditions that so generally prevail at that season. That and good cultivation during their growing period, when the bulbs must be built up for flowering next year, is the secret of success in this and, in fact, in all bulbous plants that have a definite period of rest. Lachenalias deserve to be more generally cultivated than they are, for although not very showy, they have a quiet charm which should appeal to many plant lovers, and their requirements are very few, simply a frame or cool house where they can be kept safe from frost. Early potting is essential, and this should not take place later than the end of August or beginning of September.

Ixias and Babianas are also natives of South Africa and, like Lachenalias, are grown in cold frames until they begin to throw up their flower-spikes, when it is an advantage if they can be removed to a light and airy greenhouse. They are, however, later in flowering than Lachenalias, and it is not usual to pot them until the end of September or beginning of October.

Tritonias also require the same cultural conditions. They are very beautiful and usually last a long time in flower. There are several species, but *T. crocata* and its varieties are those generally met with in cultivation.

Veltheima viridifolia and *V. glauca* are also natives of South Africa, and are at present beginning to throw up their flower-spikes. They are not showy plants, but they appeal to many people. Their flowers are not unlike Lachenalias in shape, and are of a rosy red colour, the red being spotted on a greenish or yellowish ground colour. If a batch of seedlings are raised, they vary considerably in depth of colouring in the perianth. Increase is effected generally by means of offsets, but seed should be more generally used, as by selection it should be possible to get improved forms. Like the other plants mentioned, these plants are valuable from the fact that they can be grown in a frame or cool greenhouse. They also require a resting period, but they should be kept growing as long as possible, gradually drying them off as the foliage turns yellow.

Trachelium cœruleum is a very useful blue-flowered plant for the greenhouse or conservatory. Seed if sown now will produce useful flowering plants for the stage towards the end of the summer. There is a white variety which is worth growing for the sake of contrast. Plants raised in this way last year and flowered in 6 in. pots make fine specimens 3 ft. to 4 ft. high if grown on the second year. Where such plants have been kept they should now be potted into 8 in. or 10 in. pots. They grow freely in ordinary good potting compost, as they are strong-rooting subjects, and they enjoy copious supplies of water and liberal feeding when they have filled their pots with roots. At all periods of their cultivation they only require cool greenhouse treatment.

Calceolarias of the large carpet bag type are great favourites with many cultivators, although personally the writer prefers the smaller-flowered and more elegant type represented by Cibrani, Allardii and various other strains. In any case the large-flowered varieties, where grown, should

receive attention as regards repotting as they require it, for good specimens demand ample pot room and rich compost. Some old mushroom-bed manure is ideal for mixing with the potting soil. Failing this, some dried cow manure rubbed through a sieve is excellent. The plants should only be potted moderately firm, as they enjoy a free root-run. At all times they must have cool, moist conditions, and they may with advantage be given a much lower temperature than that usually accorded them. In fact, I have grown some fine specimens by standing them at the bottom of a north wall during March, where they only had the protection of a canvas screen at night and during inclement weather. They are very subject to attacks of aphid, which should be prevented by frequent fumigation. Plants of C. Cibrani raised from cuttings last autumn should also be repotted as they require it.

J. COULTS.

Royal Botanic Gardens, Kew.

National Rose Society: Annual General Meeting.—The great success of the National Rose Society continues unabated. There was rather better attendance than usual at the Annual General Meeting held at the Caxton Hall, Westminster, at which Mr. E. J. Holland presided. That the members are satisfied with the conduct of affairs was fully evident, for the Annual Report was adopted without discussion and the meeting proceeded smoothly and pleasantly. That this faith is justified may be seen from the report, which records an increase of 1,604 in the membership during the past year—a record for this flourishing Society and, we imagine, a record unequalled by any other special floricultural society. The Council are not inclined to rest content even with 7,386 members, and on its behalf the President urged a further increase. The great success of four of last year's shows was remarked upon, particularly the autumn show, while it was regretted that, owing to unavoidable circumstances, chiefly climatic, the experimental New Rose Show on July 28 was not successful. The law of death has removed two very old members. Mr. George Paul was one of the very oldest members, and had continued his active interest in the Society almost to the day of his death. Mr. John Hart, another old and enthusiastic member, was a particularly successful amateur exhibitor. Turning to the financial statement, the President said that they regretted having to depart from the old custom of paying all debts during the year they were incurred, but during 1921 it had been found expedient to carry over the printer's bill of

£1,058 18s. 5d to 1922. This was principally for "The Enemies of the Rose" and the "Selected List of Roses," two popular and valuable publications, the stock of which was largely for issue to the present year's new members, so that, strictly, most of the amount belongs to 1922 and not the Society's year now ended. The Hon. Treasurer felt confident that by the end of the year this item would be cleared off and there would be a good credit balance. The announcement that the Dean Hole Memorial Medal has been awarded to Mr. Samuel McGredy was received with applause. It was regretted that Mr. McGredy had found it impossible to come from Ireland personally to receive the medal. Mr. McGredy has raised a record number of new Roses and holds over fifty of the Society's gold medals. Quite the most popular motion before the meeting was the vote of thanks to the genial Hon. Secretary, Mr. Courtney Page, to whose hard work was attributed much of the success of the Society. In responding, Mr. Page expressed the indebtedness to the trade and other members who had proposed so many new members, instancing Mr. H. R. Botwright, who had proposed seventy members. In giving some interesting particulars of the office work, he said that altogether over 2,500 letters had been answered and of these 1,300 dealt with technical questions. Of the 7,386 members, he said, only thirty-one had not paid their subscriptions, and he felt confident that this small number would be diminished before long. After the meeting the members were entertained to the customary tea, which was followed by an exhibition of the Society's latest lantern slides.

FORTHCOMING EVENTS.

February 6.—National Chrysanthemum Society's Annual Meeting, to be held in the Floral Committee Room at the Royal Horticultural Society's Hall at 6.30 p.m.

ROBERT SYDENHAM LIMITED	

SINCE our reference, on January 21, to Mendel's Law, we have been inundated with articles upon the subject, all calculated to make clear its principles to the ignorant. Mendelism was, of course, introduced rather as an illustration than for its own sake. It is very doubtful whether the exposition of genetics can fairly be said to come within the province of a gardening paper. Be that as it may, it is certain that, to obtain the knowledge essential for plant breeding upon Mendelian lines, it would be necessary to purchase a text book upon the subject and to study it carefully and at leisure. For the benefit of

those, however, who are still puzzled by the occasional use of such words as Dominant and Recessive, it may be well to explain that Mendel's discoveries (and the discoveries of those who have carried out further experiments on the lines he laid down) have suggested that, just as all matter was by the Atomic Theory divided into ultimate particles called Atoms, so the proportions, colouring and other attributes of animate objects may ultimately be reduced to factors upon the recombination of which, or occasionally upon the removal of one or more, change of character depends. If, now, two plants or animals quite distinct in at least one outstanding particular be crossed, the factors will all combine together and the progeny (F_1 , as breeders call it) will normally be, approximately, a mean between the two parents. This fact is now well appreciated by poultry fanciers, who know that first crosses between two breeds combine in fixed, if unequal, proportions the characters of both, but that if bred from again, the progeny are what they are pleased to call mongrels.

Now, to come to the facts which are chiefly of interest to the plant breeder, if F_1 is self-fertilised, the resultant progeny (F_2) will show an enormous variety of offspring differing widely in every respect in which the original parents differed. Experiment has shown, none the less, that there is order in the variation. It is generally found in practice that the first cross (F_1) inclines somewhat to one or other parent as regards each particular character. That particular tendency may be said therefore to be dominant. Now in F_2 it will be found, under normal circumstances,

WHEN RE-MODELLING THE ROCK GARDEN THE BEAUTIFUL ANDROSACE LANUGINOSA AND ITS VARIETY, LEICHTLINI (ILLUSTRATED), SHOULD BE BORNE IN MIND.

themselves. Thus in briefest epitome Mendel's Law for the benefit of those who have not found time to follow modern developments in genetics.

Garden Economy.—There will be found in our Correspondence columns a reply to an article in our issue for January 28 which advocated the cultivation of dwarf Peas to the exclusion of those varieties which need sticks. There have been for long enough dwarf Pea enthusiasts and those who are quite the reverse; so much depends upon temperament, the supply and cost of sticks, soil and exposure, and the climatic conditions of each season. Nor is the question of labour all upon one side. Dwarf Peas, especially if unstaked, are scarcely suitable for ground which is, for any reason, at all foul, since they are much more troublesome to keep clean than those on sticks. Again, the garden owner who employs little labour outdoors may perhaps persuade the lady of the house or some of the frocked indoor staff to gather Runner Beans or Peas if neatly staked, where they would absolutely refuse to turn over haulm on the ground and perhaps disturb a few slugs or a worm or two! It will be seen, then, that economy in the garden is many-sided and must be thought out individually, since individual circumstances vary so enormously.

The Point of View.—Our correspondent, it will be noted, takes exception to the mention of "highly paid" labour in the original article. No sane person would, we think, consider gardening a well paid profession. Were it better paid, it would, no doubt, attract to the profession many who, as things are, regretfully turn their backs upon it and set their faces to openings less congenial. Still, if labour is not highly paid it is expensive, which from the point of view of the garden owner amounts to much the same thing. With an income approximating, on the average, to that he enjoyed pre-war, and with enormously increased taxation—how enormous has been the increase in taxation on incomes of any size the manual worker seldom stops to consider—the private employer of labour has, with terribly diminished resources, to pay his staff wages which, though relatively less than eight years ago, are actually very considerably more.

ROCK GARDENS AND ROCK GARDENS

A comparison of styles and a plea for a most satisfactory form of gardening which is available in little space.

NO phase of ornamental gardening can give more pleasure or charm in its infinite variety at a minimum of cost than rock gardening nor is there one which more forcibly appeals at the moment when tropical plants, or any plants demanding artificial heat, are practically taboo. There is none too better able to display tasteful arrangement by the artistic eye and ministering hand. Rock gardening is for all, from the cottage to the castle. None gives greater scope for planting than the judiciously arranged rockery in its varying aspects, ranging from warm and dry to cool and moist from sunshine to shadow; or provides finer facilities to cater for rooting tastes of the great alpine family including the more refined and delicate members of the bulbous tribe.

Of the making of rockeries there is much, of varieties many from the simple clearing and suitable planting of Nature's handiwork such as seen long ago in an old rectory garden on the Cotswolds, "rock-ribbed and ancient as the sun," to an ambitious endeavour of comparatively recent date aggressively conspicuous in a suburban garden, resulting in two huge symmetrical mounds nicely balanced on either side of a porched entrance, chiefly composed of soil larded with stone splinters vertically stuck in with that splendid regularity a French *chef* employs with his larding needles,

the crowning glory of the latter examples being something in the way of a noseless Venus on the one excrescence ogling an armless Adonis on the other. There are, of course, many triumphal stages between the two, and some wholly outside either, yet to the first named, although but a memory, one's heart goes out.

Back to the Cotswolds! What induced "t' Paason" to start converting that rough outlying Bramble-beset bank into a thing of beauty when rock gardening was practically gardening *incognito* or how he contrived to lure "Old Jarge," his gardener, from the sanctity of the walled-in old world kitchen garden and his beloved Tea Roses in "t' grinbus" is not known, but there was no question of its having resulted in an unqualified success. Such, too, might be oftener repeated to-day where natural opportunities occur. It was at this, the winter season, the twain started clearing the oolite strata embedded in a shelving bank, and there is no better time for the work than this dull time in our gardens, but the planting which succeeded the clearing in spring, it must be added was such as no orthodox gardener of to-day with a plethora list of alpine plants before him would be guilty of. It merely consisted of a few of the lesser Thymes, the little Harebells, *Campylopusium*, in white and blue; the old *Aubrietia deltoidea*, with a few of the commoner

Sedums and *Saxifragas*, not forgetting a host of self-sown seedlings of *Alyssum saxatile*, the inimitable Gold Dust of spring. All were inserted between the oolite ribs in a way that, as seen before leaving those dear, lonely Cotswold Hills of Gloucestershire, they made far stretching colonies or pretty cushion yards, or feet, in extent. It was all so perfectly simple but as a bit of natural adornment simply perfect and soul satisfying.

It is a question if, on the larger scale of rock building, there is anything finer in its way than Pulham's *chef-d'œuvre*, carried out for the late Lord Ardilaun when converting St. Stephen's Green into a public park for the citizens of Dublin. Anyway, no more honest praise could be afforded than its having been taken or rather mistaken, by a transatlantic visitor for Nature's handiwork, and that when Nature was in her happiest mood. Wholly different, less striking, but more interesting to the lover of hardy plants generally and alpine plants in particular, is the alpine border more

recently constructed from huge boulders by Mr. J. Kearney, the lately retired superintendent of the same picturesque city park. This contains quite an interesting collection of alpines nearly, but not obtrusively, labelled that all who run may read, and the value of such an educational factor

LARGE, WATER-WORN BOULDERS IN A ROCKERY AT ST. STEPHEN'S GREEN, DUBLIN.

ELABORATE ARTIFICIAL ROCKWORK AT ST. STEPHEN'S GREEN. DESPITE THE ARTIFICIAL CONSTRUCTION, ADMIRABLE IN ARRANGEMENT.

is endorsed by the many seen taking notes of species and varieties. For extent and variety in rockwork making and planting, nevertheless, the Royal Botanic Gardens, Glasnevin, some two miles from the G.P.O., Dublin, are in Ireland *facile princeps*, of which, more anon.

Rock gardening has "caught on" in our fine old Irish gardens around Dublin, apart from notable examples further afield. Some comparatively small examples, such as that of Mrs. George Mitchell's, Ardlui, Blackrock, afford some very happy inspirations for those interested. In this particular instance, although the rocks are naturally enough disposed, and tastefully planted, one gets in the forefront of it all, as it were, the keystone of character in one huge partly sunken rock, wearing evidence of its glacial migration, leading one to infer that the whole thing is a natural outcrop. Where water can be introduced it, of course, adds its own inimitable charm, and this is pleasantly illustrated by the pretty bog garden at St. Stephen's Green. Even on quite the small

scale—where the rocks appear to dip into but a very small pool—a plant of the unique Water Hawthorn. *Aponogeton distachyon*, now proved perfectly hardy, gives graciousness peculiarly its own. Many things flourish in the rock garden which merely exist on sufferance in the hardy flower border, while in not a few cases there is to

be found some rarity of the high alpine world spoken of by Mrs. Sigourney as

“ Meek dwellers mid yon terror-stricken cliffs,
With brows so pure and incense breathing lips ”

condescending to make itself quite happy and at home. K.

LILIUM AURATUM AT BRODICK

The following notes on the successful cultivation of Lilium auratum outdoors should be of general interest

FAMOUS as a summer resort and for the new varieties of Potatoes raised by Mr McKelvie, the Island of Arran on the Firth of Clyde has in a minor degree gained distinction for the culture of *Lilium auratum* in the open. Although favoured in winter by the absence of severe frost, the climate in summer and early autumn varies but little from that experienced on the Ayrshire

Some of the spikes were 6ft. high and carried from twenty-five to thirty-eight perfect blooms. The bulbs are lifted every fifth year, when the old soil is removed and a fresh compost of turfy loam, leaf-mould and a little old manure substituted. Beyond a surface dressing of blood manure each year when growth is beginning to show no further treatment or protection is given. The best results are obtained in the third and fourth year,

SOME OF THE WONDERFUL SPIKES OF FLOWER.

coast, fifteen to twenty miles to the east, and few gardeners would select Ormidale as an ideal spot for growing *Liliums*, as the situation is high and exposed to the north-east. When these conditions are taken into consideration, the results achieved are all the more surprising and suggest special treatment and skill.

The picturesque little village of Brodick nestles near the base of the mountain range that stretches across the island from west to east, and about a quarter of a mile from the village the grounds of Ormidale slope downwards towards the golf course and the main road. Plant life in the locality is vigorous and healthy. The cottage gardens, with their display of Roses, Sweet Peas, *Antirrhinums*, Poppies, etc., are the admiration and envy of the summer visitors, but the beauty of the garden at Ormidale is only visible at close quarters. There is a wide expanse of lawn in front of the house, and here the *Liliums* are grown in a series of beds which form a semicircle enclosed by a rustic pergola. The beauty of the setting is accentuated by a background of *Wichuraiana* Roses that come into bloom simultaneously with the *Liliums*. When seen in September last there were 180 heads in full bloom.

represented in the present cycle by 1921 and 1922. As the lawn both at back and front has a sharp dip, a photograph of a comprehensive character could not be taken, and the reproduction only shows the centre beds.

The gardens are worked by a young gardener single-handed, and on the occasion of the Caledonian Society's Exhibition at Edinburgh last September he staged seventeen heads of *Lilium auratum* which for size and purity of the blooms were a revelation alike to horticulturists and the general public. The judges awarded a silver medal but the exhibit was value for the higher honour. The smallest head carried thirty-two blooms and the largest forty-five and not one had suffered from the long journey by steamer and train, as the gardener had gone to the trouble of tying the blooms individually.

Encouraged by his success at Edinburgh he intends to put up a larger exhibit of *Lilium auratum* at the International Show at Glasgow in August. It is possible however that the same standard of excellence will not be obtained, as it is only in favourable seasons that the blooms are fully opened by the end of August. J. Y.

SOME BEAUTIFUL SALVIAS

In these days, when heat must be economised, the following notes on the Salvias flowering outdoors on the Riviera should be of interest. All those mentioned may be flowered in winter in a cool greenhouse, though some sorts need space for their accommodation. Many would, doubtless, succeed outdoors on our south-western seaboard.

IN days before the war Sir Thomas Hanbury used to send each year a list of the plants and shrubs in flower at La Mortola to the gardening papers. This year, if any such list is sent, it would be the most misleading and in some ways the most unsatisfactory record; for the long-prolonged drought has prevented so many things from growing on the Riviera that I am inclined to believe that many northern gardens would make a far better show—at least on paper. This month, I think, must be called the month of *Salvias*. Only one that I know of is fragrant to any ordinary nose, but there are so many that flower bravely in mid-winter that they are among the most indispensable of shrubs of medium height. They are showy and hardy, so free, so diverse in their stature and their colours. The pity is that they go by so many names in different gardens! The scarlet *Salvia splendens*, now past its season, is replaced by *Salvia gesneriflora*, a still finer thing and of much larger growth. It attains a height of 5ft. or 6ft. and is covered with bold spikes of large flowers for quite three months. There is a charming soft salmon-pink sport of this shrub that is quite indispensable in spring. Its colour is apt to fade in the full sunshine, so this lovely flower should be planted in the shade of an Orange tree or some other sheltering growth. *Salvia involucrata* (or *Salvia Bethelli*) is also another fine bold shrub, with rose-red flowers and brown bracts, of much beauty for a long period. It is slightly less hardy than *Salvia gesneriflora*, but only suffers when there is exceptional cold.

There are two charming violet-flowered or violet-calyxed *Salvias* that are quite indispensable to the winter garden. *Salvia eriocalyx* has white flowers that spring out of violet hairy calyces. The growth is neat and terminates in long sprays of dainty flowers. *Salvia chamaedrifolia* has brown calyces and rich violet flowers. This shrub is of rather loose and scrambling habit, though of particularly pretty foliage, and it is seen best either tied up to a post or to an Orange tree and cut back after flowering in March. This delightful shrub was one of the very few that withstood that terrible wind frost of 1920. The only one of the red-flowered section that stood that cruel night was the old and dainty *Salvia coccinea* so constantly in bloom at all seasons and yet so often neglected and forgotten. Two more scarlet-flowered *Salvias* of great beauty there are, and I never have satisfied myself as to the name of one, which has red-brown hairy calyces and small bright red flowers in long upright spikes. The foliage and growth are particularly bold and handsome and it deserves a place in any good garden. The other is well known under the name of *Salvia frutescens* and is almost a tree in stature with bold heads of scarlet bracted flowers in the style of *Salvia splendens*, but in branching clusters like a scarlet Lilac. In the months of November and December this tree *Salvia* can be quite glorious in its branching luxuriance, but it is such the most tender of all the *Salvias* I have mentioned and does not come to perfection every year. The fragrant *Salvia rutilans*, I have kept to the last. Its pineapple-scented leaves are well known in English gardens, but I have never seen it flower so

freely there as it does here; but though pretty, it is not of outstanding merit, and I should not know where to end if I embarked on the many and varied *Salvias* that can grow on these sunny shores and enjoy these periods of severe drought. In fact it is the absence or the presence of the autumn rains that on the Riviera determines the number of plants in flower on New Year's Day. I should think

there are fewer plants in flower this year than almost any other January I can record. The hardy plants that need the autumn rains to start them are still dormant, and the succulents and the more tender shrubs that enjoy heat and drought are in unusual beauty. I trust they may escape from serious damage this winter of 1921-22. E. H. WOODALL.

Winter-Flowering Shrubs at Glasnevin

BY LADY MOORE.

THAT handsome evergreen shrub, *RAPHIOLEPIS DELACOURI*, is supposed to be a hybrid between *R. ovata* and *R. indica*. It is of French origin; the plant in this garden was purchased from the well known firm of Chenault. It is an evergreen of thick-set, rounded form, about 4ft. high. The leaves are leathery, broadly oval, dark green,

and most welcome when it opens in the bleak month of December.

RHODODENDRON DAURICUM opened its cold-toned lilac flowers on January 3, quickly followed by *R. MUCRONULATUM*, whose larger flowers are of the same tint. *R. PARVIFOLIUM* has neat little heads of flower of a more pleasing colour, more blue and less magenta.

THE PINK-FLOWERED HYBRID, *RAPHIOLEPIS DELACOURI*.

The flowers are a bright rose pink produced in a stiff, upright panicle or raceme 3ins. to 4ins. in height. This plant has developed from a very small pot plant to a fine shrub. Supposed to flower in early summer, in May, 1921, it flowered sparsely, and again in November. It is to-day (January 14) covered with fully opened flowers, as well as many unopened inflorescences. It is planted in a sheltered border, nearly due south; toft, behind it there is a wall, with trees to the east which shade it from the morning sun. The flowers were uninjured by 8° of frost. It does not object to the poor, stiff limestone soil of Glasnevin, which in this part of the garden is not shallow.

SALIX DAPHNOIDES ACUTIFOLIA is a Willow which comes into flower in December. The catkins are borne on slender, arching twigs, violet coloured, covered with a plum-like bloom. The male catkins are very narrow and of a bright silver. This Willow is a native of Russia and Turkestan, and is also called *S. pruinosa*. For decorative work this Willow is useful and lovely,

Blue Primroses have been in flower since November. *Crocus Imperati* in short grass makes a gallant show on a sunny morning.

Of flowering shrubs *PRUNUS SUBHIRTELLA AUTUMNALIS*, sometimes called *P. Miqueliana*, is the bravest and best. It opened its first pretty pale pink flowers in the last week of October, and in spite of heavy rain, gales and 9° of frost, continues industriously to keep its branches a shower of bloom. Its usual flowering period here is from November to April. This most delightful and desirable shrub was imported from Japan by the late Mr. T. Smith, of Daisy Hill Newry. It should have a place in every garden, large or small.

[*Prunus subhirtella autumnalis* was illustrated in *THE GARDEN*, October 8, 1921, page 502.—Ed.]

CORNUS OFFICINALIS, also a native of Japan has been open since the first of the year. Its miniature yellow flowers, thickly set all over the twigs which branch gracefully, give the bush a very pleasing effect. It is most useful for table decoration, being light and graceful, and lasts well in water.

AUTUMN'S MATURER GLORY

The Cultivation of the Gladiolus.

IN America, where it has a special journal devoted to itself, published each month, the *Gladiolus* ranks as high as the *Rose* and the *Dahlia* do with us. No wonder! for it is one of the noblest ornaments of the summer and autumn garden, capable—when rightly used and grouped in masses—of forming the visitor by its brilliance. Did someone murmur the word "stiff"? Perhaps, but a stiffness with a great charm about it as the flowers stand in soldier-like erectness. Moreover, the stiffness is very largely lost when the spikes are merged one into another by the massed effect of great clumps in the garden.

When cut and placed in water in the house, this very stiffness becomes a virtue. Well placed in tall vases, with either their own or a little foliage of the common *Flag Iris*, there is nothing else in their season so imperial in appearance.

Culturally, all varieties and species appreciate best a loamy soil that is inclined to be heavy. A yellowish loam that is greasy to the touch is the ideal. Few of us have this, but fortunately the corms will do well in any soil that is in good condition and with which a little extra trouble is taken in preparation. The need is sufficient stiffness to retain water (so that the roots do not find themselves in an absolutely dry state), but drained, aerated and warmed by the addition of abundance of sand and grit. It is very often recommended to use cow manure for these flowers, well incorporating this with the soil at about 1ft. below the surface. While this treatment cannot be surpassed for a light soil, do not overlook the fact that in soils approaching the tenacity of clay stable manure with its quota of straw is from all points of view to be preferred. Naturally, dry soils are far "hungrier" than moist ones, and when dealing with these the quantity of manure used should be considerably increased.

It is scarcely possible to work the soil too deeply during the winter months previous to planting, 3ft. being none too much to trench, while the surface should be thrown up rough and left in ridges so that the maximum amount of weathering can take place. Whatever the nature of the soil, trenching cannot fail to improve its condition, make it warmer and more fertile and improve the drainage. I may seem to be labouring this point of soil preparation considerably, but it is one of the really vital items in culture, and far more depends upon its thoroughness and efficiency than all the after care that can be given to the plants. Lay your foundation well and truly in thorough and generous soil cultivation and you may plant your corms with the assurance of gorgeous spikes of flower, almost leaving the plants to grow themselves through the subsequent stages of their life. After culture, of course, is needed. I do not mean that last sentence literally, but so great is the importance of soil preparation that it overshadows all else until the great moment of planting comes.

This is best done towards the end of March, though, of course, we must be guided by the state of the soil and the state of the weather. The *Gladiolus*—in my experience—is far hardier than is generally supposed, the *Childsii*, *Lemoinei*, *nancejanus*, *gandavensis* and *brenehleyensis* sections all standing unharmed through the winter in light soils if left in by mistake, though inevitably there are losses if this is done as a regular thing. Still, it conveys a hint for the planter, and early

planting—or as early planting as is practicable—cannot be too strongly commended. Space enough must be given for sun and air to play their part, 12 ins. to 15 ins. apart and 4 ins. to 6 ins. deep being suitable where grown among other plants, or 6 ins. apart where grouped in borders. Use a trowel for planting; it is quite as expeditious as a dibber, and does not leave a hard ring round the edge of the corm. Corms vary in size with variety, and for a general rule one will not do better than cover the corm with soil to twice its depth.

As soon as the foliage has speared its way through, lighten the surface soil up with a Dutch hoe, one of the *Gladiolus* grower's greatest friends. A light and friable condition of the surface acts in exactly the same way as a mulch and keeps the soil, where the roots are, evenly moist. Water must be regularly supplied whenever drought occurs, though it is a mistake to be constantly pouring cold water on the ground. Thoroughly soak when it is required, hoe the surface the following day, giving each corm a little drop of liquid manure, and then leave until, by inserting the finger into the earth, one finds that water is really required again.

After flowering is completed, leave the corms in the soil for as long as the weather enables you to do so; then lift, and after a suitable period in a dry frost-proof shed, store in fibre until spring returns.

When lifting in autumn is the opportunity to propagate—or rather, one of them, for seeds are equally reliable, though slower. When you dig up the older corms you will find innumerable small offsets (spawn, as they are sometimes called), and these, varying from the size of a small pin's head to a pea, should be collected and "sown" in boxes of soil in the greenhouse, where they are grown on until large enough to be put out in drills in the open ground. Do not attempt to keep these cormlets dry through the winter; they are too small, and will simply perish. Sow them thinly as though they were seeds and keep as cool as possible through the winter. This, of course, reproduces the parent true to type, but if new varieties are desired, the only method of procuring these is by inter-crossing existing types while in flower and raising the seedlings from them to flowering size.

Fertilisation is quite a simple matter, readily performed by anyone; but great care is necessary to protect the stigma with muslin both before and after the operation. This excludes insect visitors of the winged type, and is sufficient for general purposes, though, of course, it is ineffective against thrips and minute insects, which may carry other foreign pollen grains to the receptive stigmas. This is a negligible factor, however, and can be disregarded, though it helps to explain occasional variations that cannot otherwise be accounted for.

Diseases and pests are not a serious worry to the *Gladiolus* grower, though wireworm is apt to be troublesome. Old gardens are usually free of this except where new soil is imported. The autumn trenching assists greatly in harrying these destructive creatures, for birds are constantly at work all winter, searching out and destroying them. Soil fumigation and trapping in slices of potatoes are also invaluable aids in reducing their numbers.

Red spider occasionally attacks them during hot summers, and very soon ruins the appearance of the plants, but this can always be held in check by occasional syringings with water and by hoeing the soil so that the roots do not become dry. The *Gladiolus* fungus (*Myriococcus fusan*) is a very destructive pest where the attack is severe, and prompt and drastic measures should at once

be taken to combat it. Burn all affected plants at once and dress the soil freely with flowers of sulphur, afterwards trenching 3 ft. deep, as this buries the spores of the fungus that may still be living too deeply for further harm to result. Before planting, if you have any reason to suspect that corms are

infected with this foul disease, dip them in a solution of one part of formaldehyde to five parts of water. They should remain in this for about two minutes, and it is a wise precaution to take with all newly purchased corms if you hold a large and valuable collection. H. W. CANNING-WRIGHT.

A NOTE ON THE POMEGRANATE AS AN ENGLISH WALL SHRUB

THE hot and sunny summer of 1921 almost made the Pomegranate forget how different is our climate from that of its original habitat and of its present normal culture. In many of our gardens—such as Matheron Palace, as the accompanying illustration shows—it not only bloomed freely but made a very good effort at fruiting. Yet Mr. George Nicholson, in his "Dictionary of Gardening," tells us that "in Britain, even its

THE POMEGRANATE RIPENING FRUIT OUTDOORS AT CHEPSTOW.

flowering is chiefly limited to the most exceptionally favoured localities," and I well remember when, at the end of a previous hot summer—1911, I should think—the Matheron Palace example behaved as it has recently done, that I mentioned the Pomegranate as a desirable garden subject to Mr. William Robinson, who assured me its bloom was so uncertain that he did not think it worth using in this country. I retaliated by mentioning Canon Ellacombe's free-flowering double variety at Bitton, and added that I had not only enjoyed much bloom from my own plant, but that it was actually developing its fruit. He was frankly incredulous, and I only brought conviction to his mind by posting him a specimen—I will not say edible or of imported size, but fully formed and coloured.

A native of Cabul and Persia, *Punica Granatum* became widely distributed and cultivated by the ancients. It was in early mediæval times so well established as a useful if not high flavoured fruit on both the north and south shores of the Mediterranean up to its most westerly limits, that our

Monkish writers on garden matters—who, as translators and adapters of their Latin predecessors, dealt more with southern than northern cultivation—not infrequently mention it under various spellings, such as "poumgarnet," while in 1533 Elyot, in his "Castel of Helth," tells us that "Pomegranates be of good iuyce and profitable to the stomacke." Shortly before that time it had obtained decorative popularity in England as one of the heraldic devices favoured by Catharine of Aragon, and so long as she was the favoured wife of Henry VIII his nobles and courtiers found place for it among the royal emblems which they embroidered on their bed-hangings or carved on their woodwork. Lord Chamberlain Sandys used it in both materials. With the arms of Aragon and Castile it may yet be seen much repeated on the wainscoting of the gallery at the Vyne, in the form of a twig with a leaf on one side, a flower on the other, and terminating with a fruit, split so as to show some of the seeds. In the inventory taken after Lord Sandys' death in 1541 we read of: "A riche bodd of greene velvet and saten, garnished with roses and pomegarnettes," which had no doubt been kept in the background in 1535 when King Hal, having divorced Catharine, brought her successor, Anne Boleyn, to visit his Chamberlain at the Vyne. Probably the Pomegranate plant had not at that time been cultivated in England, as we are told that it was first introduced here about 1600 by John Gerard. Its form, substance and colour commended it to the poets, so that Elizabethan Greene sings of "cheekes like faire pomegranade kernels, wash't in milk," while Georgian Thomson praises it in the lines:

"Nor, on its slender twigs
Now bending, be the full pomegranate scorned."

Which shows us that the characteristics of its habit at fruiting time were known to him, but whether in England or not is another matter. Treated as a wall shrub it is hardy, in many parts of England. Purton, near Swindon, is by no means a mild wintered place, but I well remember, in the summer of 1894, seeing a bloom-sprinkled plant growing right up the wall of a farmhouse in that parish. That is what caused me to plant one in the following year at Matheron, a warm and sheltered spot in Monmouthshire, near the Severn Estuary. It did not take many years to reach the eave of the two-storeyed building I set it against, and no winter frost, although it has encountered several that were quite severe, has ever even cut it back. It is, of course, deciduous, although its dark, glossy, substantial leaves have an evergreen look about them. I think that it has had some flowers every year, but in damp, cool summers only a few. Only the sun heat of a summer such as the last one brings forth its scarlet blooms in quantity and enables some of the blooms to set and swell the fruits as we see them growing on their boughs in the photograph taken and kindly lent by Mrs. MacNab, whose husband, Major MacNab, bought the place of me a couple of years ago. H. AVRAY TIPPING.

INSECT EGGS AND SPRING SPRAYING

"If insect ravages could be brought more under control by lessening the number of these destructives whenever they appear in excess, the benefit would exceed everything of which at present we have any conception."

—JOHN CURTIS, 1859.

MANY insect pests of fruit trees pass the winter in the egg stage, and these eggs are always deposited by the parent in such a position that the young on hatching find their food within easy access. Examination with a pocket lens of a few long wood shoots of last year's

INSECT EGGS—SHOWING POSITIONS FAVOURED FOR DEPOSITION.

A, *Apple sucker*. B, *Aphis*. C, *Red Spider*.

growth and a few short fruiting spurs of Apple will probably reveal the presence of some of these insect eggs. Those most likely to be located are the eggs of Apple aphid, red spider and Apple sucker. Three species of aphid are well known as attacking the Apple; they are: *Aphis pomi*, the permanent Apple aphid; *Aphis sorbi*, the rosy Apple aphid; *Aphis avenae*, the Apple-Oat aphid.

In the autumn these species all oviposit on the shoots of the Apple, selecting their sites according to the species, the eggs of the permanent Apple aphid being usually found on maidens in nursery beds and on "water sprouts" and weaker growths in established trees, while those of the other two species are found evenly distributed throughout the trees on the fruit spurs. With the former the distribution of eggs is very frequently local, two or three maidens in a row being badly infested with eggs and the others around them being quite free from infestation. The same state of affairs occurs in gardens and plantations where single trees only may be badly infested. In the case of the rosy Apple aphid and the Apple-Oat aphid, on the other hand, the eggs are deposited on the fruit spurs singly or two or three together, and the distribution is fairly even throughout the plantation.

Aphid eggs are small, black and shining, and are elliptical in shape. In length they are about .6mm., that is to say, arranged end to end, forty would measure about 1in. The general shape and arrangement are shown in the accompanying figure (B).

Since it is practically impossible to distinguish between the eggs of the different species mentioned, inferences only can be drawn, and these from the positions the eggs occupy on the shoots. The permanent aphid eggs are in dense masses among the hairy outgrowths on new wood, particularly on water sprouts, and are often so numerous as to give the shoot quite a blackened appearance. The eggs of the other two species are generally located at the bases of the buds on spurs or partly hidden in the crevices and scars about the spurs. They are probably never found in such numbers as in the case of the permanent form.

The eggs of the red spider are spherical and reddish; they are found in little clusters around the bases of buds, in the downy pubescence on the buds or in the scale scars on fruit spurs. They

are very minute, measuring about .16mm. in diameter, or side by side 160 would measure about 1in. In cases of bad infestation these eggs may be so numerous as to give the bases of the buds quite a reddish tint. They are fairly evenly distributed throughout the tree and the plantation (Fig. C).

Apple sucker eggs are described by Theobald in "Insect Pests of Fruit" as follows: "The ova, when first laid, are almost white, then they become creamy yellow, and later assume a faintly rusty red hue before hatching. . . . They are elongated oval in form, somewhat pointed at the ends, one of which is produced into a thin process which is apparently curled under the egg and cannot easily be seen unless the ovum is very carefully removed." A. H. Lees—"Annals of Applied Biology" Vol. II, No. 4, page 251—has shown that there is another process at the other end of the egg which "is hollow and is inserted through the bark into the cortex of the twig where it ends blindly." It is suggested that there may be some physiological connexion between the egg and the Apple twig since the condition of development of the latter seems to influence the date of hatching of the former. According to Lees, "The eggs are laid in greatest number at the base of the fruit spurs, often sheltering under the edge of the scale scar; frequently one side of the spur has more eggs laid on it than the other. . . . As a rule there are but few eggs laid on the vegetative shoots of one year's growth. This occurs only in cases where there is considerable crowding of eggs on the fruit spurs."

Sucker eggs may often be found side by side with aphid eggs in the scars on fruit spurs, their colour and shape, however, makes them readily distinguishable. In length they are a little shorter than the eggs of aphid, but are apt to be somewhat stouter; they are about .4mm. long, that is, about sixty to the inch.

These insect eggs on fruit trees hatch in most cases when the buds are showing green, that is, about the end of March or beginning of April. Referring to the hatching of Apple sucker, Theobald (*op. cit.*) states: "The small larvæ coming from the ova at once ascend to the buds, and if they are not sufficiently open they may be seen seated on the buds waiting to gain entrance."

Where examination reveals vast numbers of eggs present and it is desired to apply a wash immediately caustic soda or limewash could be used. For general infestations, however, spraying with soap and nicotine or with lime-sulphur at the dormant or delayed-dormant stages, will usually give satisfactory results. It is now a well-established fact that no definite date or dates can be advocated for applying sprays, the intimate relationship between the stage of development of the buds and the activity of the insect pests necessitating some more exact method of timing. This is obtained by dividing the spring development of fruit trees into definite well-marked stages. Two only of these are important as regards spraying and insect eggs; they are the stages known as *dormant* and *delayed dormant*. The dormant stage is that before the flower buds burst in spring, and probably the best results are obtained by spraying when the buds have started swelling and so loosened the scale leaves, but show no trace of green. The delayed dormant is the stage when the flower buds have swollen so as to show just a

trace of green at their tips; this on examination is seen to be the young leaves in a tightly folded and compact mass.

If lime-sulphur is used against insect eggs a spray at a strength of one gallon of concentrate to ten gallons of water may be applied at the dormant stage or one in twelve to one in fifteen at the delayed dormant stage. For soap and nicotine probably the best mixture consists of 1 per cent. of soap to .025-.05 per cent. nicotine, using soft water as a basis. The liquid potash soap as supplied by Messrs. The MacDougal Yalding Co. of Yalding Kent, is undoubtedly one of the best and most convenient soaps on the market. It gives a speedy mix which is important from the time-saving standpoint, and is most satisfactory either for garden or plantation use.

HERBERT W. MILES, N.D.A.

The Hosts of Silver-Leaf Disease

As the extermination or mitigation of this increasingly prevalent disease depends upon an understanding of its distribution, the following observations are worthy of careful study.

UNFORTUNATELY this disease has caused considerable trouble and anxiety to growers of fruit during recent years, and, although the annual loss is difficult to estimate, growers at the present season are busy cutting out infected wood.

Of trees attacked the Plum is by far the most susceptible, the following varieties being given in order of susceptibility: Victoria, Czar, Monarch, Washington, Belle de Louvain, Bryansstone, Gisborne, Diamond, Magnum Bonum, Early Orleans, Pond's Seedling, River's Early Prolific, Pershore Purple, Yellow Egg, Blaisdon Red and Kent Bush.

There appear to be very few records of the Damson being attacked in this country, and it would seem that the stocks upon which Plums are

STEREUM PURPUREUM FRUITING ON THE BUTT OF A FELLED POPLAR.

worked play some part in the degree of susceptibility. Further observations on this matter are necessary over a number of years before any definite conclusions can be arrived at with accuracy. Certain growers assert that *Victoria* upon its own roots is more resistant than when worked.

In the United States it is stated that Apples fall victim to silver-leaf disease, and cases of Apple infection in this country are not by any means rare. As far as my observations go the variety *Newton Wonder* appears to be susceptible, while silver-leaf on the varieties *Lord Suffield*, *Ecklinville*, *Bramley's* and *Grenadier* has also occurred with some frequency.

Other fruits usually attacked in this country are *Cherries*, *Red and Black Currants*, *Gooseberries*, *Apricots*, *Peaches* and *Nectarines*, the three latter coming next in susceptibility to the Plum.

In the past it has been usual to associate the silver-leaf disease with fruit trees and certain it is that from an economic standpoint the disease on this class of plant is usually more serious. Nowadays it is usual to consider the causal fungus of silver-leaf to be *Stereum purpureum*, and although

there may be some who do not hold this view no satisfactory evidence has yet been found to suggest otherwise. This fungus is often found on flowering shrubs and forest trees.

Of shrubs I am inclined to think that the *Portugal Laurel* is very susceptible, for certain it is that whatever part of this country is visited, silver-leaf infection of this plant may be found. The *Laburnum* and, in certain districts, the *Almond* are also attacked.

Coming to larger trees, the fruiting bodies of *Stereum purpureum* are often found on the *Oak*, while *Alder*, *Poplar*, *Willow*, *Birch* and *Elm* are attacked.

To a less extent I have also observed *Stereum purpureum* on *Sycamore*, *Acer campestre*, *Hazel*, *Beech*, *Mountain Ash*, *Hawthorn* and *Sloe*.

Growers who have wood of the above-mentioned kinds near to their fruit trees would be well advised carefully to examine it. Should the fruiting bodies be observed, they should be destroyed to prevent further infection to fruit trees. Fructifications of both the bracket shaped and flat type are found on these various hosts.

OBSERVER.

GARDEN ECONOMIES

Labour saving. Some very present helps in trouble.

I READ lately in a daily paper that a very reverend Dean had the day before made a remark in one of his public utterances to the effect that "taking one consideration with another," he thought "sinners" were more interesting people to meet than "saints." However this may be, I often thank my stars that I am a gardener in my own garden and not in Paradise—yes, even as *Parkinson* would have it, with such marvels as the *Vegetable Lamb* and, inferentially, the *Barnacle Goose* tree thrown in. How horribly dull and uninteresting it would be, simply to have to perform, in a sort of clockwork way, a certain number of routine actions with the assured result that all would be well, that no writing on any label would ever be obliterated, that no stick would ever break, and that flowers would need no gathering. Even just for one moment suppose you could begin life again with your experience of the lower world as part of your stock in trade, would your lament on leaving Paradise still be the same? Would you say *Milton* was wholly right in putting the words he did into your mouth as the awful thought of leaving came over you? Difficulties often prove but the raw material of pleasure when things go wrong; and go wrong they do even in the best ordered gardens. It is the common lot of all. There is no monopoly of this in either *England*, *Ireland*, *Scotland* and *Wales*. I know those who garden at *Myddelton House*, *Mount Ussher*, *Monreith*, or *Pentlyn Castle* would bear me out, if asked "Ah! but let me now come down from the clouds and touch solid earth. Let me put on one side the greater "annoyances" which necessitate uncommon men and women to deal with them. Let me touch earth and let me for one moment think of some lesser troubles which touch lesser people, such as labels, sticks and scissors.

There is still wanted a perfect label. I am very doubtful if one will ever be invented, but I am convinced the difficulties are considerably less than those which confronted the alchemists of older time in their search for the *Philosopher's Stone*—only one wise man (*Moses*) they say ever found it and he kept the secret to himself after grinding the golden calf to powder. Who ever finds the ideal label now will have no need to keep it to himself

Let him manufacture the label by millions and then advertise them almost at what price he likes to an eager and expectant world, and his zinc, lead, iron, glass or wood will be transfused into gold or "fishers." This applies more especially to labels for outside; for all purposes of indoor utility I have come to the conclusion that celluloid, cut and fashioned according to the wants of the particular garden in which it is to be used, is difficult to beat. It can easily be cut into any shape or size that is wanted. Labels made from it last for ages, and ordinary pencil writing is as plain as it was at first, twelve years afterwards; they can be cleaned again and again with "Monkey Brand"; they are pleasant and easy to write upon, and I use them very largely indeed for making notes about seedlings, both indoors and out of doors; celluloid labels are a boon and a blessing, and after twelve years experience I can strongly recommend them. One of the things I admire in so many brethren of the "blue apron" is the dexterity with which they cut flowers with their knives. I have to use scissors or perhaps I should say flower-gatherers. I have used several makes and I have seen others, but the *French Cueille-fleurs* of *Vilmorin* of *Paris* are a long way the best in my opinion. I was introduced to them by as natty a gardener as ever lived—the *Rev. Edwyn Arkwright* of *Algiers*—who was the first to find the white form of *Iris unguicularis* and whose "Telenny" strain of *Sweet Peas* was one of the first, if not the first, of the early or winter-flowering strains to be offered to the public. I must have had the pair which I now use thirteen or fourteen years and their plating is almost undimmed and their sharpness has hardly abated at all. One point about them of practical value is that they can be made either to hold or to loose a flower when cut. It depends on the part of the blade which does the deed.

The name of *Charles Wolley-Dod* was once a household word among all of us who fancied ourselves. Part of the garden at *Edge Hall* consisted entirely of raised borders, somewhat on the principle of that which was advocated in *THE GARDEN* for *January 21*. I remember it well and also how I tried to copy it when planning my own. The reason, however, that I have introduced this

famous name is because he was an advocate for iron sticks and stakes. I still have a large number that I bought at his instigation, but (one would not think it possible) they somehow or other get fewer in number. As leaden labels have been found useful for melting into bullets so I fear these iron sticks and stakes do come in handy for other purposes than their legitimate one. They theoretically ought to last for ever, but like so much else, these sticks—

"Do not what they ought,

What they ought not, they do"

(*Matthew Arnold, slightly altered.*)

If I remember rightly these supports at *Edge* were painted a dull dark green and so were mine at first, but devil a coat have any of them seen for this last twenty years, and really I don't think they look any the worse without it and they are quite as useful.

I had them made of all lengths, beginning at 2ft. and going up to 6ft. Some were made for a wonderful plan I had for growing *Sweet Peas* on stout string, threaded through holes in 6ft. stakes which were pierced for the purpose. What can be more eloquent of the change that the last quarter of a century has seen on the development and cultivation of this splendid useful annual? I advocate iron sticks and stakes. I have hardly ever caught them bending and I have never caught them breaking. *Mr. Samuel's* giant *Delphiniums* and *Messrs. Ballard and Beckett's* tallest *Michaelmas Daisies* have no terrors for them. If only plants could speak in human language what a chorus of united request would the owner of every garden have rising up every spring from his herbaceous borders. "The iron age has come, good master, the iron age has come." "If expense could be ignored, what might we not do?" that master might reply.

Again, who is there with hundreds of pots of different "stuff" to tie up with but one pair of hands to do it, who does not sigh at the weary task before him? It is a tedious job while it lasts. It is one of the newer annoyances that has arisen since so much has been grown under glass. The gardener who wishes to shorten the task should try some of *Allwood's* rings. They are a grand labour-saving device and as they have been in use at *White-well Rectory* ever since *Allwood Brothers* brought them out I can say from personal experience that they are a very present help in trouble. A stick is put in the centre of each pot; on this you can hook, by an ingenious device, one or two, or as many rings as are required in order to keep pace with the plant's growth. They are as neat and inconspicuous as any sticks or supports can be. They last for years. They take up little room when stored away. We tie them in sizes in bundles and hang them on nails on a wall. *Spondite*, which I referred to when I tried to describe our special *Whitewell* frames, cannot be omitted. A broken pane is a serious trouble in winter time, and must be attended to at once. We find *Spondite* very handy to pop in, and no harm has resulted from two or three bits that have been doing substitute for eighteen months, having stood our *January* and *November* snows this winter and also come through the intense heat of last summer "as right as a trivet." Like *Spondite*, the last help that I am going to mention, has not been under observation very long, but so far it has justified its purchase. I refer to a composition fuel called "Ovoids," which looks for all the world like dull black duck eggs. No problem is more perplexing at the present time than the heating of greenhouses. I imagine there is no one who cannot reel off at once the names of friends who have had to make changes in this direction. Economy is the order of the day at *Whitewell*, as elsewhere. Can we get

a sufficiency of heat at a less cost than in 1919 and 1920? is the question of the hour. One catches at straws. An advertisement of "Ovoids" at 48s. a ton, delivered at any station in England and Wales led me to give an order. Although it is too soon to make anything like an ex-cathedra pronouncement, I can say that if a constant low temperature is what is required, they are full of promise. They are wonderful lasters, which in itself is a recommendation, but they do not seem to give as much heat with the same draught as

coke, or coke and anthracite mixed. When they are first put on the boiler fire they give off a good deal of smoke, which has a peculiar smell, suggesting tar as one of the factors in their composition. This smoke seems to be the fly in the ointment. Will it be too much for our chimneys? So far we have not been burning it long enough to say, as we had to start coke before it had time to do much harm. When summer comes and we have burnt it in the warm days of March and April we shall know more.

JOSEPH JACOB.

THE FORMS OF IRIS UNGUICULARIS

The quite exceptional floriferousness of this beautiful, if variable species, make the following notes doubly interesting.

LADY MOORE'S article on this species on page 44 touches on many points of interest, and I am grateful to her for the opportunity of explaining the point of view which I adopted in dealing with the Iris genus. I am almost afraid that I am looked upon as a botanist, though, of course, I am nothing of the sort, but merely an amateur gardener, blessed perhaps—or should I say, cursed?—with an enquiring mind, which urges me, when once I have a plant in cultivation, to raise seedlings of it in order to see what happens. This habit of raising seedlings has shown me how useless it is to describe any Iris species in the minute way in which a correspondent describes "the lovely Iris unguicularis" on page 45, or to demand that it should be "accurately described as regards colour." Experience of many seedlings has shown me that no two are exactly alike either in colour, shape or marking. I remember, too, how every little piece of a number which were once sent to me from the island of Cephalonia produced flowers of a different shade of purple and how the markings varied on each one.

Once this infinite capacity for variation is realised it becomes a question whether one will follow the example of some botanists, who stroll out after lunch for a country ramble and return for an early cup of tea with ten or twenty new species of Blackberry, or whether we shall content ourselves with a rather wide definition of a species embracing within it all local forms or varieties, and excluding all others which differ structurally and not merely in colour or in size or in the exact outline of some part of the flower or of a leaf. Mendelism has shown us that even an extreme form may be expected to breed true when self-fertilised, yet no one, I imagine, would make into a distinct species the form of Iris Pseudacorus, of which the flowers have no brown markings on the yellow ground, but which breeds true to that character.

Nothing is easier than to take one individual specimen and measure it minutely in centimetres and millimetres and to call it the type, and then to describe as a distinct species every individual which varies in the least from it. If I had adopted this method in dealing with Irises, I could doubtless have filled several columns in some supplement to the "Index Kewensis" and seen my name attached as author to whole strings of new species. Variations in colour and shape and marking occur frequently among plants of Iris unguicularis of Algerian origin, but none of them possess, as far as I know, the curious bosses or swellings at the base of the segments of the flower, which I have always considered typical of I. speciosa. For this name there is no botanical authority and it seems as though Glasnevin has a different plant under this name. It would be interesting to hear from Lady Moore whether the early flowering pale blue form has these

swellings. I should fancy it would not possess them and that this early form is really of the Algerian race and not Greek, as I believe the later-flowering form with the bosses to be.

When Janka gave the name "cretensis" to his plants, he made no mention of I. unguicularis and merely separated it from I. humilis, which is to all intents and purposes an I. graminea with no stem and a long perianth tube. If he had called it the cretensis variety of I. unguicularis, no one could have objected, and we could have added a list of local varietal names, such as græca, attica, cephalonica, asiatica, lazica, etc., for all of which I could at one time have produced plants. Even then we should have had to admit under each of these names numbers of colour forms, and from time to time intermediates would have turned up, which would not belong, strictly speaking, to any one of these local races. For instance, I raised a very beautiful series of dwarf seedlings from a pod of seed I obtained from a Cephalonian plant crossed with pollen of the Cretan form. The colour and markings vary in each individual plant to an extent which would doubtless astonish those who are accustomed to think of I. unguicularis as a plant of which all individual examples are alike in every minute detail.

No satisfactory answer has yet been found to the question "What is a species?" but the infinite variety found in nature seems to show that it is safer so to define a species as to allow it to comprise many local forms than to confine the description to one individual. Some years ago now I tramped for a month on the eastern side of the Adriatic in search of Irises, and it was instructive to see how the pallidas down by the sea grew 3ft. high and how they gradually dwindled in height the greater the elevation became, until near the top of the Velebit Mountains at 4,000ft. they were less than 2ft. in height, with leaves like those of a small Chamæiris. The proportions remained unchanged when the plants grew side by side in my garden in Surrey, but would it be reasonable to make a fresh species for every 3ins. additional height?—W. R. DYKES.

FORTHCOMING EVENTS.

February 16.—Meeting of the Linnean Society of London at 5 p.m. Manchester and North of England Orchid Society's Meeting.

February 17.—Eastbourne Horticultural Society's Meeting.

THE BLUE ASIATIC POPPIES

Though only of biennial duration, these plants have rare charm and distinction.

THE seeds of these plants must be sown when fresh; stale seeds will not germinate. When ripe seeds are obtainable, if sown immediately under glass (a little heat is beneficial), they germinate readily. Germination, also, is fairly even, the seedlings making their appearance well together. The Meconopsis like peat, and I find this a good material for sowing seed in, as well as for the well-being of the resultant plantlets; allow a generous proportion of sand, and some leaf-mould or mellow loam as well. Being water-loving plants, neither seeds nor seedlings should lack a sufficiency of moisture in the soil. I have had plants which, having been overlooked for a few days, had flagged so much for want of water that the leaves hung limp and apparently lifeless; but a few hours after an application of water every leaf had resumed its upright position. It is surprising to behold the difference the lack and due provision of water make to these plants! At no stage of growth, therefore, should Meconopsis be kept waterless. The seedlings should be grown on in pots indoors until they are sturdy enough to be planted in their permanent shady positions. Heat is not required during growth, which is certainly rather slow, but very sure. Even if the seedlings show reluctance to make rapid development for the first year, they will make up for it afterwards in the production of larger plants and greater floriferousness. These beautiful flowers are worth waiting for, although, unfortunately, they are only of biennial duration.

The chief value of the species of Meconopsis, apart from their great beauty, lies in the fact that they give us a blue Poppy—a glorified Shirley in appearance and substance, which has indeed caught and held the reflection of the blue skies of its Himalayan home. Several blue Poppies, I ought to have said, of which M. Wallichii is undoubtedly the best and easiest to grow. This plant shows its charm even in the seedling stage, when the prettily cut green leaves become covered with a multitude of long golden hairs which hold the drops of water so charmingly that they have the appearance of sparkling diamonds. This becomes more and more noticeable as the plants mature. The foliage certainly forms a handsome setting to so beautiful a flower. Another fine blue species is M. aculeata, the Prickly Meconopsis. The name faithfully describes the appearance of the plant; the flowers vary considerably in colour, many blossoms being of a splendid dark blue. M. sinuata latifolia resembles the foregoing in all but the leaves, which are less divided. M. racemosa produces its blossoms in a raceme in which it differs from its brethren; but its colour is a lovely blue. These species are all readily cultivated. There are others, however, of equal merit, but of different colour. A beautiful yellow is M. integrifolia, a gracefully disposed majestic plant of 4ft. M. paniculata bears handsome flowers of a pale sulphur yellow. It is but little grown, however, which is a pity. Another smaller species with red flowers, M. punicea, is almost unobtainable. The British representative in this section of the Papaveraceæ is the yellow or orange coloured M. cambrica, single and double, of our Welsh mountains. This is, of course, quite perennial and will willingly naturalise itself among the stones in the rock garden, either in sun or shade. Yes! even in the trodden path.

H. L.

A Bright Display at Vincent Square

THERE was a very interesting show at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on the last day of January. Greenhouse flowers predominated, but there were several pleasantly arranged little rock gardens and also sufficient shrubs to show that the outdoor garden need not be devoid of flowers even in the dead of winter.

The principal exhibit was a very large collection of greenhouse Primulas by Messrs. Sutton and Sons. Not only were all the plants models of cultural skill but the arrangement showed how very decorative these dwarf plants are. The bowls of stellata varieties placed on stands table-high were especially charming and these contained plants of such sorts as Coral Pink and Improved Giant White, which excited a deal of deserved admiration. Of the

delightfully fragrant *Daphne indica rubra* as small, useful bushes and several *Mimosas*, with many greenhouse *Azaleas* and *Camellias*. The two last named were also staged in quantity by Messrs. L. R. Russell, Limited, and with them were plants of *Begonia manicata* and sprays of *Prunus triloba*.

Chrysanthemums are not yet flowers of a past season, for Mr. S. Aish was able to contribute quite good blooms of such sorts as Enfield White, Percy A. Dove and Heston White.

The little rock gardens were somewhat similar in design, but not sufficiently so as to be monotonous. Messrs. Waterer, Sons and Crisp displayed in theirs beautiful little groups of such dwarf *Iris*s as *ungicularis*, *u. lilacina*, *reticulata* and *sindjarensis*, while the mass of *Crocus versicolor* Cloth of Silver was very fascinating.

Very good blooms of *Iris reticulata* were also

A BEAUTIFUL CHINESE PRIMULA, SUTTON'S IMPROVED GIANT WHITE STAR.

fimbriata varieties, Reading Pink, Giant Crimson and Coral Pink made welcome masses of colour. The rose-shaped double flowers of Queen of the Pinks were also admirable in their colouring and profusion.

On a table space Messrs. Sutton had an attractive display of spring bulbs growing in bowls of fibre. There were many *Hyacinths* and *Narcissi*, with smaller numbers of *Lachenalias*, *Lily of the Valley*, *Anemones* and *Crocuses*.

Carnations were again an important feature and the collections by Messrs. Allwood Brothers, Messrs. Stuart Low and Co., and Mr. C. Englemann contained excellent flowers. Such pink varieties as Eileen Low, Laddie, Delice, Cupid and Boadicea were all very beautiful, while vivid colour was provided by Lord Lambourae, Edward Allwood and such. Chief among the Perpetual-Malmaison varieties were Mrs. C. F. Raphael and Jessie Allwood, of splendid colour. Besides Carnations Messrs. Stuart Low and Co. again had the

prominent in the exhibit of Messrs. J. Cheal and Sons where a number of Cushion Saxifrages and various conifers were well placed. Near by there was a model of a sunk garden and a rockery by Mr. E. Dixon.

Iris histrioides of beautiful blue colour and a breadth of *Liranthus hyemalis*, with Christmas Roses and a collection of conifer sprays, were included in a contribution by Mr. G. Reuthe.

The best alpinos were a goodly patch of *Saxifraga Bursoriana magna* in the small rock garden by Messrs. Skelton and Kirby. The blooms were very clean and pure white. They also had *Saxifraga Elizabetha*, bearing pale yellow flowers, adjoining plants of *S. Aizoon notata*, *Hamamelis mollis* and *H. arborea*, with a variegated *Elæagnus* and several *Ericas*, were very attractive.

Besides a rock garden planted with *Sedums*, *Saxifrages* and other plants, Messrs. Wm. Cutbush and Sons had *Ericas*, *Conifers* and a number of small, very glaucous plants of *Eucalyptus Gunnii*.

There were no floral awards of merit, but a card of cultural commendation was awarded to Mr. A. M. Robinson, Eastgate Manor, Chichester, for unusually large *Violets* of the varieties Mrs. D. Lloyd-George, Princess of Wales and Marie Louise.

New Apples.

Laxton's Pearmain.—This is a very handsome late dessert Apple. In outward appearance it is much like an unusually dark coloured Cox's Orange. The flesh is yellowish and the flavour first rate. We were informed by the raisers that it is a cross between Wyken Pippin and Cox's Orange and that the trees are of upright habit, robust growth and that the variety fruits freely. Award of merit to Messrs. Laxton Brothers.

Ananas Reinette (Pineapple Reinette).—An uncommonly late dessert Apple that possesses the true Pineapple flavour. Shown by Mr. E. A. Bunyard.

Reinette Grise de Saintonge.—This is a somewhat large dessert variety of conical shape. The skin is dark red and russety and it is of good flavour. Shown by Mr. E. A. Bunyard.

William Crump.—A few years ago this small conical Apple, which was raised at Madresfield, received a first class certificate, but unfortunately it has not yet proved to be sufficiently free cropping to be valuable. It is beautifully coloured and of first rate flavour. Shown by Mr. E. A. Bunyard.

A seedling Apple of excellent appearance was shown by Mrs. Alice G. Harrison, Hattondale, Wellingborough, who stated that it was raised from a pip taken from a colonial Newtown Pippin. This was questioned by the Fruit Committee, who considered it to be almost identical with Northern Spy, and as this variety is not suited to our climate, no recommendation was made, though there does not seem any reason why a seminal variety should not be fruitful here. The fruits submitted to the committee were most beautifully coloured and of excellent flavour.

GLOBE FLOWERS

There is something about the Globe Flowers which delights the real gardener's heart, yet they are not cultivated as much as they should be.

NO excuses need be made for using as the heading of this short article the English name for the plants which are about to be described. *Trollius* is the Latin or botanical name, but did ever anyone say to another, "Come and have a squint at my *Trolliuses*?" Is it not always, "Come and see the Globe Flowers?" This is quite as it should be. Without being too pedantic, if the word may be used in this connexion, it is always well if there are good old English names attached to plants to use them in English gardens.

"Globe" is at least as old as John Parkinson's time. In his very famous and often-quoted book the "Paradisus Terrestis" he has a picture of our native British form under the name of "The Globe Crowfoot". This was its usual name in Southern England. In "the Northern countries," he says, "it is called *Locker goulous*". This is interesting because the word "Boits" or "Bouts" is given as a synonym in Nicholson and other dictionaries, and one wonders if it should not have been "Locker goulous" or "Lockin Gowan" meaning a "closed-in bud or flower," for in Britain and Holland and in Prior "Boits" is undoubtedly the Marsh Marigold.

Parkinson's graphic description is so good that we can take it as a general description of the family, remembering that we now have in our gardens of pleasure a dwarf form, "acaulis" and also more

CORRESPONDENCE

A NATIONAL DAFFODIL SOCIETY?

open and orange-coloured forms like asiaticus and its derivatives. "It hath many faire, broad, darke green leaves next the ground, cut into five, six, or seven divisions and jagged besides at the edges; among which riseth up a stalke, whereon are set such leaves as are belowe, but smaller, divided toward the toppe into some branches, on the which stand severall large yellow flowers, alwayes folded inwards, or as a close flower never blowing open, as other flowers doe, consisting of eleven leaves for the most part, set or placed in three rowes, with many yellow threads in the middle, standing about a greene rough head, which in time growth to be small knops, wherein are contained blacke seede; the root is composed of many blackish strings." These leaves or, as the unbotanical might call them, these petals are really sepals. The true petals are found inside these and are much smaller and stand up in a more or less conspicuous manner round the more central stamens and seed vessels. The seed is black as Parkinson describes it, and it has this characteristic: if it is sown as soon as it is ripe it will germinate in a few weeks, but if it is kept till the following spring it will remain dormant a whole year. Hence if anyone buys seed in the ordinary way from a dealer, they must not condemn the seed and throw the seed-pan and its contents away if no seedlings appear in the course of a few weeks. The old writer's description of the root system is just as accurate as the rest. The roots are composed of many blackish or dark-coloured strings. One might make a very decent false beard out of the roots of a Globe Flower plant. This gives a good idea of their appearance. In a garden the chief essential for a plant to go "from strength to strength" is a moist or somewhat damp position. They prefer rather stiff and rich soil with plenty of humus, and, growing naturally in grass, they like a modicum of shade; at all events it is well to avoid too much sun unless the ground immediately round them can be kept cool. Autumn is the best time to break up old plants and to buy new ones, although there are some who advocate February or early March. If they are planted at this last date, particular care must be taken to guard the young foliage from drying and cutting winds and to see that the roots have plenty of water if there should come a dry time. They will do well in similar places to those in which the Japanese Irises (*Iris Kamperi*) flourish, by brook sides or in semi-marshy land, but not, we believe, where water is continually lying. It will be a surprise to those who do not go with the times to know that there are now a great many seminal varieties on the market, and that one new species has latterly been added from China. The species which have given us pretty well all our varieties are three in number—*Trollius europæus* (our native Globe Flower), *T. asiaticus* (the Asiatic Globe Flower) and *T. altaicus* (the Altaian Globe Flower). It is impossible to say how many varieties are in commerce, but Mr. G. W. Miller, of Wisbech, who more than anyone else seems to have made a speciality of them, and who has repeatedly staged them at the Tuesday shows of the R.H.S., offers in his last catalogue no less than thirty-seven. The following half-dozen can be confidently recommended as some of the best. In pale yellows, Lemon Queen and Lichball; in deep yellows, Earliest of All and Ophir; in orange shades, Fire Globe and Flame. In addition it ought to be mentioned that at least two varieties in time past have received awards of merit from the R.H.S. These are Orange Globe and napellifolius. They are both very good, but Flame and Lichball have left them behind. Well-grown plants of any of these should average from 2½ft to 3ft in height.

SEVERAL Daffodil growers have written me asking why I do not send a few lines in support of the proposed "National Narcissus Society." I should have done so long ago only I am afraid I do not share their views regarding the success, and I hate to sound a discordant note. Why the holding of two shows—similar to those we have—under the name of "National Narcissus Society" is to turn a failure into a success is more than I can imagine, unless, of course, there are some thousands of enthusiasts withholding their support because the R.H.S. and Midland Daffodil Society do not please them. The R.H.S. may have all the faults some writers accuse them of, but to cut clear of them and go off on our own would, to my mind, be casting our only lifebelt away. I speak from a very wide experience of shows (I believe I hold a record, having attended six in one week) and I know of few shows—even country shows—that are as badly attended as most Daffodil shows are. To run a Daffodil Society successfully on two houses per year is more than I can gulp in all at once. The Dry Bulb Show, I hope, is dead. I travelled four times from Ireland to attend that show, and it was nothing but a farce; the only time our bulbs were noticed was on the occasion when the soldiers pelted each other with them, and an hour before judging time we were busy trying to make King Alfred look like Emperor so as to make up our necessary count to twenty. Judging by the many shows that I have attended and that are still in existence I should imagine we require a "gate" of 10,000 to each show to make it a success. I am, of course, assuming that we rent our own hall, buy vases staging baize, &c., and it will be a surprise to me when I see 5,000 at a purely Daffodil show. The season of the Daffodil is a short one—the date that pleases the Southern grower is no use to the Northern grower, and if the Midlander had the choice of date he would fix one that would knock out the Southerner's Trumpet and the Northerner's Poet, therefore we must have three shows at the least if every member is to be catered for, and although we are probably as far from London as any exhibitor, if the place was left to me I would select London every time. How many R.H.S. Shows have been a success outside London, and which of the National Rose Society's Provincial Shows are a patch on the one held in Regent's Park? It is no use having a Drury Lane in Kilkenny; you cannot get the audience. Of course, I may be writing with one eye on the takings and the other on the expenses, but we must have our daily bread out of it or we will not live to grow Daffodils. In Birmingham we get splendid treatment—everything to your hand and the most civil committee I have ever met with, and when we have finished our staging and judging is over we go round and see each other's Daffodils. I dare say I shall be hauled up for saying that, but I can see my empty pocket book glaring at me and it will bear me out. If a National Daffodil Society is founded I will do my best financially and otherwise to keep the lid off the coffin but I must admit I have not the hope that many appear to have.—W. SLINGER, (*Donard Nursery Company*).

I THINK your Editorial Notes in the current issue of THE GARDEN are excellent. You know I am in favour of a more comprehensive and a stronger society being formed (British Bulb Association) which, I contend, could do the work of a National Daffodil Society and could do equally good work for other bulbs besides; but if the

majority are for a National Daffodil Society I will certainly support the movement and it will then be for the bulb growers to consider the formation of a "British Bulb Association" also.—W. A. WATTS.

GARDEN ECONOMIES.

I VENTURE to assert that very few gardeners of experience will agree with more than half of Mr. S. Warner Hagen's arguments in favour of dwarf *versus* tall Peas. All will agree that the dwarf varieties have their value for early, late and catch crops, but few would care to trust to them for the season's supply. True, the stakes necessary for the taller sorts are expensive, but there is now no need to grow anything higher than 4ft., this greatly economises stakes, and I, for one, have yet to grow a dwarf Pea of which two or even three rows can compete with one row of a good strain of Autocrat—to mention only one, and that quite an old one—which is in all truth a cut-and-come-again variety of the highest table value. There are many others which would come through the trial well. In a showery season, too, both dwarf and tall alike need stakes if they are to do their best, and then I think the dwarfs would cost nearly as much in stakes and labour and the return less than with those of medium height. Vermin, too, will quickly destroy crops which lie on the soil, and often much mischief is done before it is noticed and before the crop is ready to gather. As to storage of once-used stakes, are they worth it? I generally save the best of them, since they have cost more, for thickly staking the earlier crops both dwarf and tall; but there are strong reasons why they should not be used for the summer crop on the score of both insects and fungi. For several years I have been in the habit of taking catch crops of dwarf Peas from the plot on which Brussels Sprouts are to be grown. In my rotation these follow Celery and Leeks and the rows of Sprouts are marked with stakes, and as soon as the Peas can safely be sown a drill is drawn with the hoe midway between and two or three varieties are sown and generally a good crop is taken. The Sprouts can be set out when ready and both grow well together. When the Peas are finished the haulm is cut, not pulled, and so the Sprouts get the benefit of all the nitrogen stored in the nodules of the Pea roots. Broccoli follow the main crop and the same thing is done, the haulm is cut close to the ground as the rows are cleared and, after a light surface cultivation, the Broccoli plants are set out. For seed protection I much prefer Hortico to red lead and paraffin, but the best way is to trap the vermin, and in the case of mice this is easily done by setting short lengths of board on edge to form a V with a small opening at the apex and a break-back trap set so that a mouse passing through must step on the trigger. One a short distance from each end pointing inwards will soon account for them; no bait is needed, but if baited traps are set, sprouted Peas should form the bait. The reference to highly paid labour is surely not meant to apply to gardeners? It never could and I fear it never will. The amount paid now may be higher, but the value lower, and there are a great many who would be very glad if things would again reach the old level all round. Much of the economy forced on the garden at present is not always true economy, but gardeners, as a rule, do their best under adverse circumstances.—H. C. WOOD.

POTATO NOMENCLATURE.

COULD the Editor or any reader help to settle this argument: Is the Midlothian Early and the Duke of York the same Potato with two names? I have grown them side by side on the

same ground (in 1920) and have found a vast difference when dug, but Sutton's Potato expert and buyer says they are the same thing. They are, I admit, often sold as the same thing. Perhaps some of your readers belong to the Potato Society and would clear the matter up.—H. SAUNDERS.

[If Midlothian Early and Duke of York are, in fact, synonymous, there must be more strains than one of the variety. Duke of York as many people know it is distinctly the earlier. The tubers too, are generally considered more subject to "blight" than those of Midlothian Early.—Ed.]

WHERE STOVE PLANTS GROW WILD.

I WAS interested in a note on the Loquat in a recent issue of THE GARDEN. In the Northern part of India where I am living the Loquat is freely used as a tall hedge plant—similar to the Laurel at home—also Poinsettias, which, at the moment of writing, are a blaze of dazzling scarlet, most of the plants being 10ft. high and carrying upwards of forty-five bracts. Other plants in flower just now include *Tecoma stans*, *Jasminum auriculatum*, *Ipomœas Solanums*, *Bougainvillœas*,

both *glabra* and *lateritia*, the latter makes a good hedge plant and carries a bright brick-red coloured flower; the species *glabra* smotheres great trees, like Ivy at home, and is a wonderful sight. India is, indeed, rich in beautiful creepers and shrubs which are very little known in England; the former include *Tecoma grandiflora*, *Beaumontia grandiflora*, *Banisteria laurifolia*, *Pothos Argyrites*, *Ipomœa Learii*, *Héptage madagblota*, *Antigonon leptopus*, *Poivreia coccinea*, which are considered among the best. There are no English forest trees here, but beautiful specimens are to be found in these extensive gardens of *Ficus indica*, a large spreading tree; *Tectona grandis* (Teak), *Poinciana regia* and *elata*, the latter very graceful and decorative; *Ficus retusus*, *Diospyros embryopteris*, while *Croton oblongifolius* is quite soft, high and the same in diameter; *Grevillea robusta* is found in great numbers as avenue trees, and attains a height of 60ft. and 70ft. Palms, of course, are numerous and grow almost anywhere; also Roses of every variety in commerce. The extensive lawns are furnished with neat, compact shrubs, many of which produce gorgeous flowers in their seasons particularly noticeable are *Nerium montanum*, *Justicias*, *Jatropha panduræfolia*, *Eranthemums*, *Tabina montana*, *Ixoras*, *Nandina domestica*, *Cestrum auranticum*, *Tupidanthus calyptratus*, *Pittosporum Tobira*, &c. To an Englishman who has been accustomed to tending these in hot-houses they are particularly interesting seen growing in the open as lawn trees. The same may be said of hedges and hedgerows, *Pandanus* grows wild and attains a great height; *Ageratum* also is wild and, in the ditches, reminds one of Bluebells in the distance at home. Garden hedges are formed with *Duranta Plumieri*, *Myrtus* of sorts, *Didonia*, which the natives call "railway hedging"; *Hibiscus* in variety, while *Holmskioldia coccinea* is probably the best, not so much for the leaf but owing to its many pricks and the profusion of brick-red flowers. January is a cold month here; we are glad of a good coal fire and

practically the same winter clothes that we wear in England, not to mention blankets and eider-downs at night. I hope to send some photographs for THE GARDEN from time to time of plants which I think will be interesting particularly from the Palace Gardens in the Himalayan Mountains, where art and nature are combined.—GEORGE BURROWS, *Garden Controller, Patiala State.*

THE DRY BELT (B. C.).

I ENCLOSE two photographs in case they may be of interest. [One would not reproduce.—Ed.] They are pictures of flower borders in the Okanagan Valley, British Columbia, Canada, in the district known as the dry belt, the moisture being provided by irrigation. The borders were planted this year, the colours lavender, pink and white, with a grey groundwork of *Cineraria maritima* and Pinks. More annuals had to be used to fill in with than would be needed another year. They were all in bloom when this photograph was taken—*Sweet Sultan* and *Centaurea americanus*, *Phlox Drummondii* and late and dwarf *Godetias* and white *Antirrhinums*, all of

FLOWER BORDERS IN THE OKANAGAN VALLEY.

which bloomed till the middle of November, the time of the first heavy frost.—(Mrs.) H. G. FISHER.

ST. DOROTHY.

IF the Rev. Joseph Jacob did not know who this Saint was, it is certainly not surprising that the gardeners of whom he enquired were equally uninformed. If it is permissible to make a pointed observation, it is more the business of a clergyman to know about Saints than it is a gardener's. And yet, as it happens, this particular Saint is the patron of gardeners in Belgium, and probably if the enquiry had been addressed to a Belgian, our excellent friend Mr. Jacob would have been much more successful than he was with English gardeners. Among my distinctions of foreign origin is that of *membre d'honneur* of the Royal Society of Flora of Brussels. This is supposed to be the oldest floricultural society in Belgium—it is known to have been in existence as far back as 1650, how much before, the records do not state. It is claimed to be the oldest society of its kind in the world, and was originally known as the Confraternity of St. Dorothy. In 1660 an altar was erected to the Saint by subscription of the members of the fraternity, who used on certain fête days to garnish the altar with flowers and other garden produce, and in the following year rules were drawn up, a copy of which is still in existence. In 1664 the confraternity was officially recognised by the Archbishop of Mechlin, and Pope Alexander VII granted special privileges to this ancient body of Belgian gardeners. Many

illustrious persons have been enrolled on the list of membership, both Belgian and foreign. The title continued for many years, and finally some short time prior to the year 1822 the Confraternity of St. Dorothy was changed to its present title, *La Société Royale de Flore*. Its headquarters are, and for many years have been, at the Botanic Gardens, Brussels; the secretary, M. Louis Gentil, who has many friends in this country.

And now a few words about this Saint, which may be helpful to the enquirer. In "Butler's Lives of the Saints" under date of February 6 we read that she was condemned to the most cruel torments because of her refusal to marry and to worship idols, and that, being condemned to be beheaded, she converted one, Theophilus, by sending him certain fruits and flowers miraculously obtained of her heavenly spouse. It will now be seen why the two Saints appear on the title page of the "Jardin d'Hyver," with the angel distributing flowers to them. I say the two Saints for Theophilus is also a Saint in the Calendar of the Church of Rome, although he is not the subject of a special biography in Butler, nor can I find an independent record of him in the material at hand. Like several other Saints, he appears to have two days allotted to him, viz., February 6 and October 13. Saints seem to vary according to their countries. In England St. Swithin is the watery Saint; in France it is St. Médard; so if St. Dorothy is the patron Saint of gardeners in Belgium, the French gardeners have preferred St. Fiacre for their patron, and his day is August 20. But I will conclude by asking who was St. Fiacre, and what did he do to merit canonization? Perhaps our friend who has raised the question of the female Saint will, in the course of his promenade down the Avenue of Garden Saints, be able to come across him.—C. HARMAN PAYNE.

A SUBSTITUTE FOR HOLLY IN SOUTHERN FRANCE.

WHAT an attractive little shrub the Butcher's Broom (*Ruscus aculeatus*) is when covered with its large scarlet berries. It grows very freely here, and though large quantities have been gathered during the last few weeks, there is still plenty to be found, both on the stony hillsides and also on the sandy soil under the Pine trees on the seashore. Some book which I have at home ascribes the familiar name of this plant to its being formerly used by butchers for brushing their meat blocks, and every butcher's shop in the old town here seems to possess a bunch, so perhaps in Provence it is still used for that purpose. I have several times asked the name and have in each case been told "Houx" (Holly), with, in one case, the qualification "des Montagnes." The real Holly does not seem to be known here. The berries on the Butcher's Broom here are much more plentiful than I have ever seen them in England, though the plant appears perfectly hardy at home—at any rate, as far north as Yorkshire.—R. B. HYÈRES.

[It is comparatively rarely that the Butcher's Broom fruits in English gardens, as the plants are unisexual and in most gardens only one sex is grown.—Ed.]

ENGLISH CATALOGUES FROM GERMANY!

I ENCLOSE the wrapper of Bees' latest catalogue. You will note the stamp and postmark; is it possible that the catalogues are printed and posted in Germany? Can nothing be done to open the eyes of the Government (and the Postmaster-General in particular) to the ruinous policy they are pursuing. No wonder

there is unemployment in England when we even get our printing done in Berlin!—T. S. CHANNER.

[The above is one of a number of letters we have received upon the above subject. Messrs. Bees' manager has, in the trade Press, explained that the posting of the lists in Germany was intended as an object lesson to the Postmaster-General and as a protest against the unfair competition of German seed lists which cost only about one-sixteenth of a penny to send, of which our Post Office takes the smaller half! The explanation, it will be noted, says nothing as to where these lists were printed, nor as to why they bear no printer's imprint; but the general get-up of the catalogue, especially the colour printing, strongly resembles that of catalogues "made in Germany." An interesting point is that none of the wrappers we have received includes "England" as part of the address.—ED.]

A QUIANT NEW ZEALANDER.

I ENCLOSE a few notes on one of our curious shingle plants, which may be of interest to some readers of THE GARDEN. I found a good many were interested in the *Raoulia eximia* (Vegetable Sheep), and this is quite as remarkable. Our shingle slips extend for acres and acres on the eastern side of the Southern Alps, starting well up the mountains and spreading as they come down into large fans. They look absolutely bare of vegetation, just like nothing but splinters of rock, coarse in places, finer in others. I stood on one of these fans this week and noticed a strong scent, and knowing it must be a flower, immediately began to hunt, and was rewarded by finding plants of *Notothlaspi* or the Pen-wiper Plant, as it is generally called. The leaves are arranged in a rosette and are pretty well the colour of the stones; they overlap like shingles of a roof and the whole rosette is curved like an umbrella, so that only the tips touch the ground. Thus any rain falls off into the loose shingle, where the long, thin tap-root and its long branches anchor themselves among the drifting shingle. This little umbrella plant, when the shingle is hot and its underside cool, condenses vapour for its own use, and at night when the shingle cools down more rapidly than the plant the vapour condenses on the ground, thus keeping the foliage dry and fairly well protected from frosts. The flowers come in little pyramids of white or greenish yellow colour and have a very strong scent; the only way they have, I suppose, to let insects know where they are for fertilisation purposes—as they certainly are difficult to find owing to their stone-like colouring. It belongs to the Wallflower family. Now if anyone is interested enough to wish to try seed of this remarkable plant I have marked many for seed and will gladly send some on application.—MARY DOULTON, *Shirley, Christchurch, N.Z.*

[No doubt some interested readers will wish to avail themselves of our correspondent's kind offer. The Editor himself would gladly give the *Notothlaspi* a trial.—ED.]

THE CULTURE OF THE TANGIERS IRIS.

THE fine illustration appearing along with my note on *Iris tingitana* in your issue of January 21 shows over what an extended period this fine Iris may be had in flower—from December to May. Of course, one should bring them on in successive batches, like Tulips and Hyacinths, retarding and encouraging, as the case might be.

I now give, as promised, the cultural details which rewarded us with the large quantity and fine quality of blooms we have been able to gather at Christmas-time and since. We purchased 200 bulbs in the first week of September. Using 10-in. pots, we placed seven bulbs in each pot, in a compost of three parts of roughly chopped

old loam, one of well spent and partially dried cow manure, and a good dash of sea sand, covering the bulbs to the depth of 3 ins. The pots were then plunged outside in old ashes to the depth of 6 ins. Here they sojourned until the first week in November, when they were taken out of the ashes, given a good soaking of water (they like plenty of water) and placed in a cool greenhouse, with ample ventilation whenever really open weather permitted. Later on we maintained, by fire heat, a temperature of about 50°, for they are impatient of too high a temperature, which may easily cause the foliage to shrink and wither, and thus blight one's hopes.—ROBERT MCHARDY, *West Derby.*

A VALUABLE GUM TREE.

I QUITE agree with Mr. W. Smyth that *Eucalyptus citriodora* is well worth growing where climate will permit. There is no foliage to surpass it in fragrance. I grew it on the bank of the River Plate, and the leaves, green or dry, were always most acceptable to visitors, and I wish that it would grow in the open here.—V. CALDWELL, *Reigate.*

SHELLEY, "THE POET OF NATURE."

"Somers," in his article "Spring o' the Year" (THE GARDEN, January 28, page 30), playfully charged Shelley with *suppressio veri*.

Singer, whose life was lost in Spezia Bay,
But whose brave spirit lives for evermore,
Because thy glorious songs cannot decay,
Or melt like transient waves upon the shore;

In every strain the heavenly skylark sings,
Floating on waves of music to the skies,
I hear thy soul ascend on angel-wings,
In soaring strength, to heights of Paradise.

How great thy glory when the snow-white cloud
With its pure splendour crowned the mountain's
crest.

While thy celestial songster sang aloud,
As if the sunlight dwelt within its breast!

Lover of Nature, by whom suffering men
Feeling thy nature near, forgot their pain;
Thy voice still soars o'er moor and grove and
glen,

But when shall thy great spirit come again?
DAVID R. WILLIAMSON.

THE LITTLE GARDENS AT RHEIMS.

THANK you many times, Mr. Editor, for printing my appeal for flower seeds for the little gardens of Rheims. I have had some most kind and generous replies. I do so appreciate them and the friendly way in which the donors write to me. If everyone would put their names and addresses in the letters or packets I would acknowledge them separately. I have received a most generous gift of packets of flower seeds from Cardiff—such a lot and such lovely sorts. I should so like to thank the donor. Also some kind person has sent me 2s. 6d. from Glasgow; and I have also received a delightful collection from Paignton. Will you be so kind as to let me thank these kind people through THE GARDEN. I was seized with a bad attack of influenza as I was leaving England about a fortnight ago; hence my delay in acknowledging these gifts. Rheims looks very desolate and war-racked after a visit to England and a taste of its refinements and comforts. I do hope that if any readers of THE GARDEN come to Rheims that they will feel that they have a friend here in me, and will come and see me and I will take them round the barrack villages.—VICTORIA SLADE, *Lover Eminin, Rheims.*

"THE GARDEN" AS A BOOK OF REFERENCE.

WHEN first I open THE GARDEN, each Thursday (and my newsagent never disappoints), I always turn to the Correspondence columns, and there—for how many years I fail to recall—I always find some hint worth making a note upon. For many years I never destroyed THE GARDEN and other journals, until the wife, in desperation, vowed vengeance on the lot during the time of the cleaning in "the spring o' the year." Now, I was very troubled how to preserve all this valuable information, so I commenced to go through this pile, which reached from floor to roof, and after weeks, in my spare time, I bound what I consider to be one of the most valuable books of reference it is possible for any amateur to possess.

I am greatly obliged to Mrs. Duggan for bringing this matter forward, and should like to give the method I adopted, for it was impossible to go to the expense of bookbinding, which would run into many pounds. Of course, if funds are not a consideration the usual method of binding has much to recommend it, but in my case it was economy or destruction. My special interest in gardening is very limited—so also is my time—therefore I went through many thousands of pages, dissecting those pages on rock, alpine and lises—my only study. Afterwards I collected all THE GARDEN leaves or cuttings and bound them into several volumes, securing each page just as one would secure an invoice or letter, in the patent "Stolzenberg" file. We had plenty in stock at the time, before 1914, therefore I do not know if they are still to be obtained. Probably there are many others that would answer equally as well; and when one can form a series of valuable reference books at the small cost of 9d. or 1s., this system has much to recommend it to those gardeners who are in the habit of lighting the greenhouse fires with their old numbers.

Glancing through the volumes, my eye lights upon the article of "Somers" before he was reduced to the ranks of us ordinary poor, common or garden sort of persons. Strange what a difference those two little letters ET mean; and when I read our good friend's notes I always think of the old name, for the only man I ever knew called Somers was a cobbler—an honourable name, still I like the former better. Or, again, in acknowledgment to the past memories, I again turn up the notes upon that beautiful garden behind "The Door in the Wall." My series of THE GARDEN to me is indispensable.—J. P., *Cheshire.*

["Somers" is hardly so plebian a name as our correspondent seems to think. There is a Barony of the name. As binding cases can be obtained from this office for 2s. (postage extra), and the binding should cost but a very few shillings, the expense cannot be considered great!—ED.]

THE PLANE TREES.

I AM much obliged to the writers of the notes re *Platanus occidentalis*, but am not much "forrarder." There are several Plane trees here, planted, I understand, by Repton about 1770—one of them is 90ft. high and is *P. orientalis*, I should say. In THE GARDEN, dated January 28, mention is made of a tree at Bickling Hall—of *Platanus occidentalis*—and in London's "Arboretum et Fruiticetum" (1844) I see he places several about the country. It should be possible to settle the question definitely once for all, and I shall try to make sure of the species of these trees here this year, if possible.—J. D. COLLEDGE, *Cobham.*

A 128 Page Book containing the Most Reliable Garden

"OUR AMBASSADOR"

Requisites for the successful cultivation of Fruit, Flowers, and Vegetables (post free).

CAUSTIC ALKALI. Spray Trees Now. The original winter wash kills Winter Moth, Mussel Scale, Caterpillars, etc. Removes Loose Bark, Slime Lichen, etc. One tin, 2/-; 20 tins, 32/-; 10 tins, 16 6; 5 tins, 8 6.

CARNATION MANURE. Resists Disease, Produces Strong Plants and Blooms of Fine Rich Colour. 1 cwt., 28/-; 1/2 cwt., 15/-; 28 lb., 8/-; 14 lb., 4 6; 7 lb., 2 6.

POTATO MANURE "SUCCESS." Calculated to resist disease. The Most Profitable Potato Manure. 1 cwt., 25/-; 1/2 cwt., 13 6; 28 lb., 7/-.

LAWN MANURE. Produces Grass of Good Rich Colour and Fine Texture. Discourages Moss, Weeds and Clover. 1 cwt., 25/-; 1/2 cwt., 13 6; 28 lb., 7/-; 14 lb., 4/-.

"A1" FUMIGATING COMPOUND (poison) Liquid. Ready for use. Kills all Greenhouse Pests. For use with ordinary fumigating appliances. No. 6. 10 ozs., sufficient compound for 20,000 cubic feet, 13 - 20 ozs., " " " 40,000 " 25 - 40 ozs., " " " 80,000 " 42 -

"CARVITA." Life of Carnations. Death to Disease. Recognised Remedy for Carnation Rust, etc. 1 gall., 20 -; 1/2 gall., 12 -; quart, 7 -; pint, 4 -.

BONE NITRIC COMPOUND. The Kitchen Garden Manure par excellence for Brassica, etc. Per cwt., 25/-; 1/2 cwt., 13 6; 28 lb., 7/-.

LAWN SAND & DAISY KILLER. Effectively destroys Daisies, Moss, Dandelions, Clover, Buttercups, etc. 1 cwt., 30/-; 1/2 cwt., 16/-; 28 lb., 9/-; 7 lb. sample, 3/-.

NATURE'S CHOICEST NUTRIMENT "LE FRUITIER"

The Premier Plant Food of this Century for finishing Fruit as regards Size, Flavour and Colour to Perfection. "LE FRUITIER"—The evenly balanced Plant Food. Does not leave the plant to "flag." 5 cwt. lots per cwt. 30/-; 1 cwt. 32/-; 1/2 cwt. 17/-; 28 lbs. 9/6; 14 lbs. 5/6; 7 lbs. 3/-. **BAGS FREE.** Carriage Paid on all Orders of £1 and upwards.

ANTI-FLY DUSTING POWDER. Specific for Onion and Carrot Fly, Cabbage Caterpillar, etc. 1 cwt., 25/-; 1/2 cwt., 14/-; 28 lb., 8/-; 14 lb., 5/-.

LOAM. No waste. Rich Yellow and Fibrous. Fat and Marley from New Gravels. 18/- ton for 4 ton trucks. F.O.R. Midlands.

MUSHROOM SPAWN. Prolific Brand. Highly fertilised. Fresh and Reliable. Per bushel of 16 bricks, 9/-; peck, 2 6.

TOOLS. Spades, Forks, Hoes, Pruners, Trowels, Rakes, etc., etc. Prices by Return.

BONES & BONE MEAL (Medium Grist). 1 cwt., 20/-; 1/2 cwt., 11/6; 28 lb., 6 6.

FENCING. Wood and Iron. Illustrations and Prices (Gratis).

MATS. Frost and Rainproof Materials. Winter Wind Screening, Wattle Hurdles, etc. Prices by Return.

SPRAYING MACHINES. Holder Harrison Both hands free. No. 1, hand sprayer, 34 6; No. 5A, knapsack, 120/-.

SHADINGS & BLINDS. Cotton, Canvas, Serim Tiffany and Lath Blinds. Samples and Patterns by Return.

WM. WOOD & SON Ltd., "The Royal Horticulturists,"
 TELEPHONE GRAMS BURNHAM 79 "GARDENING, TAPLOW" Garden Designers & Contractors, TAPLOW, BUCKS.

BATH'S BORDER CARNATIONS, &c.

For Present Planting.

We make a great speciality of Carnations, and our stock is unequalled. The plants are very strong, perfectly hardy, and will satisfy the most fastidious buyer. The following Sets are selected from our unsurpassed collection of 450 varieties, and contain the cream of the new and older sorts.

Set A.

One dozen extra fine varieties for 15/-, Carriage Paid.

- Celestial.—A brilliant yellow self 2 -
- Elaine.—A grand white; perfect petal and form 1 6
- Hercules.—Crimson-maroon; perfect form 1 6
- Innocence.—A lovely blush-pink 1 6
- Romeo.—Yellow, suffused and marked pink 1 6
- Isolda.—Raspberry-red, very distinct 1 -
- Salmon Clove.—Salmon-pink; clove scented 2 -
- Opalesce.—A lovely ros-madder 1 3
- Lord Tennyson.—Yellow, distinctly edged rose 1 -
- Duchess of Wellington.—Deep lavender 1 3
- Red Emperor.—Rosy-red, extra large flower 1 6
- Dignity.—Crushed-strawberry self, lovely 1 3

Set B.

One dozen choice varieties for 11/-, Carriage Paid.

- Bookham White.—Pure white, perfect form 1 3
- Glamour.—Clear bright yellow 1 6
- Vanity.—Brilliant madder red 1 -
- Caprice.—Pink, mottled red; fine form 1 -
- Contrast.—White ground, edged velvety crimson 1 -
- Jean Douglas.—A scarlet self, dazzling colour 1 -
- Queen Alexandra.—Bull-yellow, very free 1 -
- Pink Beauty.—Rich clear pink, very vigorous 1 3
- Miranda.—Salmon-pink and lavender grey 1 6
- Climax.—Bull-yellow and coppery red 1 -
- John Knox.—Dark crimson; perfect form 1 -
- Lady Greenall.—Rosy-red shading to pink 1 -

Bath's Popular Set of 12 Fine Named Varieties of Carnations and Picotees. Price 8 6, carriage paid.

BATH'S GOLD MEDAL DELPHINIUMS.

These plants are remarkably handsome in the border, and during the early summer and autumn the bold and stately masses of brilliant blue and purple produce a striking effect unequalled by any other flower.

One dozen extra fine varieties for 21/-, Carriage Paid.

- La Tendresse.—Light blue and mauve 2 6
- Lorenzo de Medicis.—Soft blue, shaded pink 2 6
- Novelly.—Royal-blue, yellow and black centre 2/-
- Rev. E. Lascelles.—Oxford blue with conspicuous white eye; magnificent 2/-
- Willy O'Brien.—Purest ultra-marine blue 1 6
- Rozenlust.—Mauve, edged Cambridge-blue 1 6
- Resplendens.—Pale blue, tinted mauve 2 6
- Mrs. Caron.—Gentian-blue, white centre 1 6
- King of Delphiniums.—Gentian-blue and plum, white eye 1 6
- The Alake.—Intense dark blue with white eye 2 6
- Pannonia.—Brilliant ultra-marine blue, white eye; distinct and beautiful. A.M., R.H.S. 1920 3 6
- Musis Sacrum.—Bright sky-blue, early 2 -

BATH'S GOLD MEDAL PÆONIES.

The most gorgeous of all garden flowers. Requires less cultural attention than almost any other plant. Exceedingly hardy, its vigour and beauty increases year by year.

Set A.

- Twelve glorious richly fragrant varieties for 25/-, Carriage Paid
- Albert Crousse.—Pinkish blush; very large 3 6
- Duchess de Nemours.—Snow-white; very free 2/-
- Mme. de Galhau.—Soft pink, enormous flowers 2 6
- Marguerite Gerard.—Delicate flesh, sulphur centre, enormous 2 6
- Lady Carrington.—Flesh; very large 3/-

PENNELLS'

FAMOUS LINCOLNSHIRE

Seed Potatoes

As supplied to Royalty, are in every way equal to SCOTCH SEED.

The following newer varieties have been inspected, when growing, and are certified by the Ministry of Agriculture as free from rogues and immune from Wart disease.

They are extraordinarily vigorous and will produce crops of A1 quality.

Arran Comrade, perfect in shape, 2nd early	Per 14 lbs. 2 9
Arran Rose first early, pale rose, etc.	3 6
Arran Victory, most prolific, super quality, purple skin	2 9
Crosader (New), the sensation of 1921 at Ormskirk	8/-
Dargill Early, first early, heavy cropper, fine quality	3 6
Great Scot, one of the most popular and vigorous	2 9
Kerr's Pink, finest quality, heavy cropper	2 6
Nithsdale (New) an improved Majestic, superb	4 6
Boderick (New), late, white, highly recommended by the authorities at Ormskirk	6/-
The Bishop, late, kidney, immense cropper	2 9
Tywald Perfection, the immune Up-to-Date, splendid quality, heavy cropper	2 6

Bags free. Carriage paid on Orders of 7 6 and over.

From the Rev. Harold Mayall, Tilsden House, Cranbrook, Kent.

From personal inspection while on a visit to Holland of Mr. Anthony C. van der Schoot's Bulb Farms and Nurseries, I can not only testify to the very high standard in which everything on this very extensive farm is organised, but also to the excellent stocks of herbaceous and other plants that he carries, especially Phlox, Decussata, Delphiniums, Chrysanthemum Maximum, Michaelmas Daisies, Anemone Japonica, Dahlias, Iris, Lupinus, Ross together with Gladiolus and Begonias. I have no hesitation in recommending his firm not only as THE VERY RELIABLE BULB FARM, but as very reliable in every respect.

MRS. PYM'S FAMOUS PLANTS

GOOD AND CHEAP. 34th SEASON.

SPECIAL OFFER of good, strong, sturdy plants. Should be planted now for success. Half lots sale rate. All post free or carriage paid, passenger train, cash with order. Catalogue free.

4d. extra for orders under 3/-.

Wintered in open. Kelway's Sprouting Kale, Curly Kale, Cabbage, Leeks, Savoys, Coleworts, Brussels Sprouts, Pickling Cabbage, Cauliflower, Broccoli, Sprouting Broccoli, Tripoli Onions, Cos and Cabbage Lettuce 100, 1/9; 200, 3/-; 400, 5/-.

HARDY PERENNIALS, very strong, transplanted, flower this year. Best strains procurable. **Achillea**, double white, 6, 1/6. **Agrostemma**, crimson, 6, 1/6. **Alyssum**, egg dust, 6, 1/6. **Alpine Wallflowers**, 20, 1/6. **Alpine Pinke**, 1/9. **Anchusa Italica** Dropmore, lovely blue, 6, 1/9; angustifolia true deep blue, 6, 1/6; myosotis-flora, dwarf lovely rockery plant, 3, 1/6. **Anemone**, Japonica, white or pink, 2, 1/4. **Anemone Pulsatilla**, most beautiful spring flowering hardy perennial followed by handsome fruit, 2, 1/6. **Anthemis montana**, 6, 1. **Aquilegia**, Kelway's hybrids, 6, 1/4. **Arabis**, double white, 1/6. **Aubrietia**, rich purple, 6, 1/6. **Auriculas**, lovely alpine varieties, 4, 1/4. **Antirrhinum**, bushy plants, lovely colours, 6, 1/4. **Brompton Stocks**, year old, 6, 1/6. **Christus Roses**, large crowns, 1/4 each. **Campanulas**, blue or white dwarf or tall, 4, 1/4; pyramidalis, two year old, 3, 1. **Canterbury Bells**, single, blue, pink, mauve, white or Dear grano hybrid, 12, 1/9; double, 6, 1/6. **Candytuft**, perennial 4, 1/4. **Carnations**, good border, 6, 1/6; separate colour white, yellow, crimson, scarlet, 6, 1/9; Grenadier, lovely double scarlet, 6, 1/9. **Centaurea montana**, blue, white or rose mauve, 6, 1/6. **Chrysanthemums**, strong rooted cutting best early, mid or late, all colours, separate or mixed, 6, 1. **Chrysanthemum maximum**, new large flowering variety excellent for cutting, 6, 1/4. **Cistus** (Rock Rose), 6, 1/4. **Coreopsis grandiflora**, 6, 1/6. **Cornflowers**, Kelway's blue 12, 1/6. **Catmint**, 6, 1/6. **Daisies**, new enormous double blooms, red or white, splendid for bedding, 12, 1/6; mixed 20, 1/6. **Delphiniums**, best named, large two year old, 2, 1/4. **Delphiniums**, grand large flowering hybrids, or light or sea blue, year old plants, 3, 1/6. **Dianthus**, Kelway's love, double or single, 12, 1/6; creeping, bright pink, 6, 1/4. **Erigeron** (stenactis), mauve Marguerite, 4, 1/6; new Quakeress, 3, 1/4. **Erysimum**, golden gem, 20, 1/6. **Forget-me-nots**, best dwarf, dark or light blue, perennial sorts, 12, 1/4. **Foxglove**, 12, 1/6. **Gaillardia grandiflora**, 6, 1/6. **Galega**, Goat's Rue, 6, 1/6. **Geum**, double scarlet, 4, 1/4. **Gypsophila paniculata**, 6, 1/6. **Helienium**, 6, 1/6. **Heuchera**, scarlet, 4, 1/4. **Hollyhocks**, lovely colours, single, 6, 1/6; doubles, 4, 1/4. **Honesty**, crimson and white, 6, 1/4. **Iceland Poppies** Excelior strain, 6, 1/4. **Iris**, separate colours, mauve, white, yellow, blue, purple, 4, 1/6. **Iris**, large flag, splendid colour, 6, 1/6. **Kniphofia**, handsome Torch Lily, 3, 1/6. **Linum** blue Flax, 12, 1/9. **Linaria dalmatica**, 6, 1/6. **Lobelia cardinalis**, 4, 1/4. **Lupins**, polyphyllus, pink, white, blue, 6, 1/6; mixed, 12, 1/9; Tree, yellow or white, 3, 1/6. **Lychnis** scarlet clareconia or Salmon Queen, 6, 1/6. **Malva**, bright pink, 4, 1/6. **Monarda**, Cambridge, scarlet, 3, 1/6. **Nepetas** Musini, lovely mauve, 4, 1/4. **Pansies**, best large flowering and separate colours for bedding, 12, 1/6. **Phlox**, best, large flowering, all colours, 3, 1/6; mixed, 4, 1/6. **Paeonies**, separate colours, 2, 1/6. **Papaver pinnatum**, rich orange blooms, 6, 1/6. **Poppy**, Oriental Queen, enormous blooms, 6, 1/6. **Passion Flower**, hairy, blue and white, 2, 1/6. **Peas**, everlasting red, pink and white, mixed, large roots, 3, 1/6. **Physalis** Giant Cape Gooseberry, 6, 1/6. **Pinks**, coloured garden, 12, 1/9; double white, 6, 1/6. **Potentilla**, double crimson, 6, 1/6. **Primulas**, hardy assorted, for succession of bloom to end of summer, 12, 3/-. **Pentstemon**, large dusky scarlet Southsea Gem and grand Excelior strain, 6, 1/9; smaller good plants, 6, 1/4. **Pyrethrum**, Kelway's, 6, 1/6. **Ribbon Grass**, variegated, 6, 1/6. **Rose Campion**, bright crimson, 6, 1/4. **Rudbeckia speciosa**, 3, 1/6. **Salvia pratensis**, lovely blue, 3, 1/6. **Saponaria**, pink rockery, 6, 1/6. **Scabious**, sweet, 6, 1/4. **Shasta Daisy**, 6, 1/6. **Silene compacta**, pink, 15, 1/6. **Stachys**, Lamb's Wool, 6, 1/4. **Stachys**, Sweet Herb Lavender, 3, 1/6. **Sweet Rocket**, 12, 1/6. **Sweet Williams**, double and single mixed, lovely colours, 12, 1/6; lovely scarlet pink and crimson Beauty, 6, 1/4. **Thistle**, Queen of Scots, 3, 1/6. **Thalictrum**, hardy Maidenhair, 4, 1/6. **Tritoma**, Red-hot Poker, early and late flowering, 3, 1/6. **Tussilago**, hardy winter Heliotrope, 3, 1/6. **Veronica**, dwarf or tall, 6, 1/6. **Valerian**, crimson, 6, 1/6. **Veronica**, blue, 4, 1/4. **Viola**, separate colours for bedding and good mixed, 12, 1/6. **Sunflowers**, new red, 3, 1/6.

Strong transplanted plants for cool house. **Agapanthus**, large blue African Lily, year old plants, 4, 1/6. **Agathæa**, blue Marguerite, 4, 1/4. **Asparagus Fern**, erect or trailing, 3, 1/6. **Begonias**, scarlet, crimson and Salmon Queen, evergreen, perpetual flowering, 4, 1/6. **Auriculas**, grand large flowering, show, 4, 1/6. **Cannas**, large two year old splendid hybrids, 3, 1/6; one year, 4, 1/4. **Celsia Critica**, 4, 1/4. **Cinerarias**, exhibition and stellata, 6, 1/6. **Eucalyptus**, 4, 1/4. **Francoa**, Bridal Wreath, 4, 1/6. **Heliotrope**, very large heads, dark or light, 4, 1/6. **Lobelia cardinalis** Queen Victoria, 4, 1/6. **Nicotiana**, white or crimson T bacco, 6, 1/4. **Plumbago**, blue, 1, 1/4. **Primula sinensis**, Kelway's Model and stellata (only colours), 6, 1/6. **Primula malacoides**, rose-lilac; Kewensis, yellow; Forbesii, pink, 6, 1/6; obovata, new giant, lovely colours, 4, 1/4. **Rehmannia**, pink trumpet, 3, 1/6. **Salvia**, Zurich Scarlet, 4, 1/4. **Coccinea**, scarlet, 6, 1/4. **Saxifraga**, Mother of Thousands, trailing, 4, 1/4. **Streptocarpus**, lovely Cape Primrose, large blooms, lovely colours, 4, 1/4.

Mrs. PYM, F.R.H.S.,

10, Vine House, Woodston, Peterborough.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Brussels Sprouts.—Make the first sowing of this excellent vegetable now and thus ensure a long season of growth, which is necessary to obtain the best results. Sow the seed thinly in boxes of light soil and let germination take place in a gentle heat, such as a newly started vinery or peach-house. When sufficiently advanced the young plants will do splendidly if pricked out on a mild hot-bed.

Shallots may be planted as soon as the soil is in a suitable condition. They prefer a light and well tilled soil. Plant the bulbs firmly in rows drawn a foot apart, with a distance of gins. or roins. from each other in the rows.

Chives.—This useful adjunct for soups or salad bowl is readily propagated by seeds or by division of the roots, which may be carried out in open weather.

Pathways in the kitchen garden, owing to the considerable wear they get, necessitate an occasional levelling up or re-adjusting. The major part of wheeling and carting operations having been finished, the matter should be taken in hand, so that it will be finished with before the pressure of sowing and planting operations is needing attention. Should any of the walks have an evergreen edging, such as Box or Ivy, any trimming or relaying should be delayed until the most severe weather has safely gone.

The Hardy Fruit Garden.

Rooted Cuttings of Currants and Gooseberries, which were put in last autumn, will pay for transplanting as soon as it can be arranged for. It is not advisable to place them in their future permanent quarters but grow them on a reserve plot for a season, placing them about 2ft. apart. Good bushy plants will develop ready for future use.

Peaches and Nectarines should soon receive what pruning is necessary, and whether this is much or little will depend to a great extent on the amount of attention bestowed upon them during the growing season previously. It should be the aim to remove as much of the old fruiting wood as possible where it does not interfere with the extension or balance of the tree. Select for laying in wood of a medium vigour having a good proportion of plump fruit buds. These may be easily distinguished from wood buds as the latter are long and thin.

The Flower Garden.

Bare Ground under trees and at times among portions of shrubberies is a matter which not infrequently crops up for solution. In a more or less satisfactory manner the plants suggested below will of times be found useful. An important point to remember before attempting any planting is to dig the ground well and work in at the same time plenty of decayed manure and leaf soil. This will enable the plants introduced to obtain a fair start, otherwise an impossible task in what are generally dry, hard and impoverished positions. Two excellent and probably the most generally used plants for such work are the lesser and greater Periwinkles (*Vinca*), and one of the small-leaved Ivies. The latter is neater and more close growing, but for covering large and uneven places *Vinca* major is preferable owing to its freedom of growth, and it also deserves mention because of its delightful blue flowers. Besides Periwinkles and Ivies we have *Eunonymus radicans*, *Malva*, *Veronica buxifolia*, *Phillyrea*, *Hypericum* and *Smilacina*. These may all be planted now with every hope of success. To obtain an immediate spring display under trees there is nothing so useful as *Primroses* and *Myosotis*, as it is now too late for other bulbs such as *Daffodils*, *Aconites*, *Cyclamen*, *Bluebell*, *Muscari*, *Snowdrops*, etc., which should be planted in the autumn.

Fruits Under Glass.

Pot Strawberries.—Where only a small quantity of plants are grown in pots for bringing along under glass, the present is a suitable time for starting them, as from now onwards the plants may be relied upon to give good results. A batch is also required where a start was made some weeks ago, to serve as a succession. The early batch are now most active in leaf and root and will take more water and syringings on bright days must be well done or red spider will soon obtain a footing on the undersides of the leaves. While removing the plants from the frames or plunging ground see that the drainage is good and remove all decayed leaves, etc. Should the soil have been broken away from

around the plants add a little good loam, doing it when the plants are not very wet so that it may be well firmed into position. Plants which do not show promise of a flower spike should at once be discarded. When the plants are in flower syringing should be discontinued until a good set of fruits has been obtained, when it may be again carried out and kept up until just before colouring of the fruits commences. Feeding of the plants should be regularly carried out as soon as the flowering period is over, and continued until the fruits are colouring. From five to eight fruits is enough for plants to carry in 5in. and 6in. pots.

H. TURNER.

(Gardener to the Duke of Northumberland.)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spinach.—Sow a portion of the early border with seed of the round variety and so obtain fresh pickings as early in the season as possible. Where Perpetual Spinach is grown the plants should be encouraged into more rapid growth by frequent stirring of the soil between the rows.

Shallots should now be planted in quantity. Choose a time when the ground is in good order and scatter a quantity of wood-ash or burnt refuse over the surface, working it lightly in with the rake. Plant the bulbs in rows about 12ins. apart.

Chives.—Clumps of these may be broken up at this time and transplanted. The young growths are esteemed for salading purposes and for the flavouring of soups.

Brussels Sprouts.—One of the essentials in the proper cultivation of this indispensable winter vegetable is to give it a lengthy season of growth. Sow the seed thinly in boxes and germinate in a cool greenhouse. Keep the box close to the glass so that seedlings of sturdy growth may be obtained for pricking out on a mild hot-bed. When once the seedlings are established the frames should receive free ventilation and thus ensure well-grown plants by the time it is safe to transfer to their final quarters. In wind-swept gardens dwarf-growing varieties should be chosen, and in this respect we find *Solidity* one of the best.

Fruit Under Glass.

Strawberries.—The earliest batch of these should now receive occasional doses of stimulants and so strengthen the fruit trusses. Where the trusses are in flower hand-fertilisation should be resorted to, as there is still a scarcity of the necessary insect life. As the fruit swells support the heavier trusses with Birch twigs.

Iggs which were started some time ago should now be allowed an increase of temperature with a corresponding increase of moisture in the atmospheric conditions. Spray the trees during the early afternoon, using tepid water for this purpose.

The Flower Garden.

Box Edgings.—The present month is the best in which to undertake the relaying of Box edges. In relaying portions that have been unsatisfactory owing to poverty or sourness of the soil, the precaution should be taken of adding fresh soil; this should help the young plants that are being inserted. Tear the old plants into small portions with roots attached and plant at a regular height above the ground level, say, about 2ins. When filling in the soil tramp firmly. Neat edgings are often indicative of the standard aimed at in carrying out the regular work of the garden.

Border Chrysanthemums.—Where it is customary to box the old stools of these plants for the winter they should now be taken in hand and the necessary quantity of cuttings inserted. Dibble the cuttings firmly into boxes of light sandy soil, and as they will be transplanted into cold frames at a later date they may at present be put in fairly closely. The cuttings will strike readily if placed in an early vinery or Peach house. Move to cooler quarters immediately they take root.

Violas and Pansies.—From seed sown now strong plants may be had ready for planting out during the early part of May, and will be found to flower profusely during the summer and autumn. The *Violas* from seed come surprisingly true to colour, while among the *Pansies* the most delightful markings and variations in colour occur.

The Shrubby.

Planting.—With few exceptions both deciduous and evergreen shrubs transplant safely at this time. Where the natural soil is cold and clayey some lighter material should be worked around the roots of the young plants. Most shrubs like peat, but where this cannot be had a mixture of fibrous loam, leaf-mould and sand proves an excellent rooting medium.

Austrian Briars.—Thin out weakly growths from beds of these plants and fork in a good dressing of short, well-rotted cow-manure. As with most Briars, little pruning is required, the plants flowering much more freely when left to grow in a natural way.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

The Epacris is a very beautiful greenhouse plant which should be more generally cultivated. Native of Australia, it is classed among hard-wooded plants. It has the merit of lasting in flower for a considerable time and the long flowering sprays are well adapted for cutting purposes. There are many named varieties, varying in colour from white, through various shades of pink, red and crimson. As they pass out of flower the plants should be cut hard back and stood in a house where they can be kept rather warm and moist—at this stage they will stand more heat and moisture than *Ericas*; a day temperature of 50° to 55° will suit them very well while they are making their growth. After cutting back they require very careful watering until they make some new growth. At this stage they benefit by being sprayed several times a day with clean water. When they have made some 2ins. or 3ins. of growth, they should be potted on into larger pots, using good sound peat and enough coarse sand to render the whole porous, and like all plants of this class, firm potting is essential. As the season advances they should gradually be accustomed to more airy and drier conditions; and as they complete their growth, they may be stood outdoors during the summer months. *Epacris longiflora*, also known as *E. grandiflora* and *E. miniata*, unlike the upright growing sorts, should not be cut back every season. It makes long, straggling growths, which are best tied into a framework. This species flowers for several months at a time, and is a beautiful plant for the cool conservatory. *E. purpurascens*, syn *E. onosmaeflora* is an upright growing species; there is also a pretty double form, which used to be a popular market plant. *Epacris* are propagated by means of cuttings, using twiggy shoots that have just finished their growth. These should be dibbled into pots of fine sandy peat, made very firm and the pots stood under bell glasses in a cool house. They are slow and by no means easy to propagate, unless one has experience of this class of plant, and it would pay a beginner to buy young plants from a nurseryman.

Bouvardias.—Where it is desired to increase the stock, some old plants should be partly pruned back and introduced to a warm moist house. As they will have been standing dry for some time, they require to be thoroughly soaked at the root. If they are kept in a temperature of 55° to 60° and are sprayed over several times a day with tepid water, they will soon break into growth. When the young shoots are about 3ins. in length they should be secured as cuttings, and these will root very readily at this time. Many gardeners complain of the difficulty of successfully rooting *Bouvardias*, but if the above procedure is followed they should have no difficulty. I may say here that many plants that are supposed to be troublesome to propagate in the ordinary way are quite easy if stock plants are put in a little warmth and the resulting young growth secured as cuttings. *Bouvardias* can also be readily propagated by means of root cuttings, although all varieties do not come true to character. *Bridesmaid*, for example, from root cuttings always gives a proportion of *Hogarth* fl. pl.

Buddleia asiatica.—Although this plant was introduced during 1874, it is by no means common in gardens, which is very surprising considering how deliciously fragrant it is. A graceful plant, it produces its long, drooping racemes of white flowers during the winter months. It is a native of India and China and is a useful plant to plant out in a cool conservatory. If grown in pots it makes nice plants, the first year, from cuttings, for furnishing the benches, and if cut back during the spring and potted on into 8in. pots they make

long branching shoots some 7ft long. They should be stood outdoors all the summer to ripen the wood. Treated in this manner such plants remain in flower for a long time in a cool conservatory during the winter months. It may be propagated by means of cuttings any time during March.

Buddleia officinalis, a more recent introduction from China may also be grown for winter flowering. It makes a stiff bush and produces very freely its lilac coloured flowers with a deep yellow eye. It is strongly honey-scented, differing very much in this respect from the delicate scented *B. asiatica*.

Tuberous-rooted Begonias are useful and popular plants for furnishing the conservatory during the

summer months. A batch of tubers should now be placed in shallow boxes, with some fine leaf soil and stood in a warm house. As they start into growth they should be potted up into suitably sized pots, using a light rich soil for this purpose. If seed was sown as advised early last month the resultant seedlings should now be ready for pricking off into pans containing light soil. If kept growing steadily and given frequent shifts, a large proportion of them should make good flowering plants for the autumn, when they make a good succession to the older plants.

Royal Botanic Gardens, Kew

include, will, if the colour of the seed is right, swell and germinate satisfactorily but their after performance is markedly inferior to that of good seed.

H. H. HALL.

Polyanthus-Primroses

The biennial method of treatment.

FEW, if any, plants are more a credit to their growers for good treatment than Polyanthus-Primroses—in other words, it is well worth while taking pains to do them well. If anyone starts with seed of a first-rate strain, like the Munstead strain of Miss Jekyll, or the Spetchey strain of Mrs. Berkeley, and follows out the advice about to be given, I feel sure they will be satisfied with the result. Put into a nutshell, it is to treat Polyanthus-Primroses as biennials. To do this in the most satisfactory manner seed should be sown *very thinly* as soon as possible under glass, either in a cold frame or, preferably, in a cool, airy greenhouse.

As soon as the seedlings are fit to handle they should be pricked out in boxes or pans and placed in a cold frame, where they must get constant attention in the way of watering and shading from very hot sun. When the plants become too crowded they must be moved to a nursery bed where they can escape the midday summer sun and, as before, be well looked after.

In late September or early October they must be moved and planted where they are to bloom. If a frame filled with nice light soil is available when the seedlings in the seed-pan are ready to be pricked out, they may be put straight into it, planting them 2ins. apart. It will save one shift. If a great space can be allowed, say, 4ins. or 5ins., there will be no necessity to move them if they can be shaded in July and August, until they are put in their flowering quarters.

After the plants have done flowering they may be thrown away, for there will be another lot coming on to take their place another year. There is no need to save any, unless something most exceptional should turn up.

Given good first-rate seed to start with, the flowers of every succeeding year will be up to the standard of the previous one. What this means anyone may see for himself if he has a bed of some grown on the old perennial system and a bed of others grown on the biennial system now advocated, side by side. The extra trouble involved in carrying out this last treatment is *not* labour spent in vain.

J. J.

THE GERMINATION OF SWEET PEAS

The writer has, in the past few years, carried out many experiments on the above subject, and his recent results have been so satisfactory and so uniform that it is thought his experience may be useful to others.

IT is admitted that some of the procedure is not commercial owing to the detail labour involved, but the enthusiastic amateur will take any amount of trouble if only he can get the very best results. It is to him that the following remarks are addressed.

In the first place, it is well known that lavenders, creams and whites (with pale seeds) usually require less moisture owing to the thin skin; and in trying to avoid having the soil too wet with the consequent danger of rotting it is usual to err in the other direction and have the soil too dry, so that frequently this type of seed is the last to germinate. It may be taken as an axiom that the sooner the seed can be persuaded to sprout the better, as the shorter the time the less the chance of any mishap.

The requisite number of 3in. pots were taken and filled with any good plain potting soil and then immersed in water until it began to percolate through the top, when they were taken out and drained. The soil twelve hours afterwards was in a considerably wetter state than would normally be judged to be safe for Sweet Pea sowing. Each pot—usually in a 3in. pot three or four seeds would be sown—has the requisite number of shallow pockets made in the soil with a pencil, say half an inch deep, and when dry fine sand has been dropped into each pocket, one seed is lightly pressed home and more sand put on until the top of the seed is just not visible.

All the seeds prior to sowing will have been chipped, with the exception of the creams and some of the lavender and mauve seeds. Of the latter, it will be found on examination that some seeds are either not mottled, or if mottled, have a slightly rough appearance, either type indicating a thicker skin than the normal, so that failure to chip these would result in such seeds being late. This varying appearance of the seeds is particularly marked in the case of Lady Eveline, and to a lesser extent, Mrs. Tom Jones. The pots are covered up to exclude light, and must be examined the next morning or at any rate, within twenty-four hours of sowing. Each seed is examined and the appearance at this stage is the crux of the whole procedure; if the moisture is sufficient each seed will have swelled and generally be much lighter in colour and will come away quite dry with no sand adhering. Every seed presenting this appearance can be put back with the practical certainty that it will germinate.

Some of the seeds may not have swelled, in which case one or two drops of water (I am speaking literally as to the drops) on each seed will hasten matters. Others may, on examination, be found to be rather too wet, so that particles of sand are adhering when they are lifted. These should be left on the top of the sand in the pockets without any covering other than the cover to exclude light

on the top of the pot, and again examined in twenty-four hours, to see that they are not still too wet in which case an extra layer of dry sand is added before the seeds are replaced on the top.

Another, and happily, uncommon appearance of a seed when examined the first time after sowing, is when sweating takes place—the skin is not really wet, but appears to be sweating. A little practise will enable this to be distinguished from the preceding case where too much moisture is present. Seeds that sweat are infertile and will not germinate. The writer professes to be able, within twenty-four hours of sowing, to tell without doubt which seeds will germinate, though he admits that he has not the strength of mind immediately to throw out those that are sweating.

If sowing has been done in the autumn the majority should, in normal weather, be sprouting in five days, when each seed is planted properly and brudly. Last October, when the weather was very warm, the writer sowed 100 seeds on Sunday afternoon and over fifty were sprouting on Wednesday morning. This, of course, is quite an exceptionally short time.

If sowing is done in the early spring it is recommended that the sprouting be done at a temperature of about 60° if possible, when the pots are transferred to a cold frame if the weather is not very severe at the time. The writer uses a bathroom cupboard with considerable success for the purpose of assisting early germination.

All this may appear to be a great deal of trouble, but for the small grower it does not take long, and the results are very interesting. Except when doubtful seeds of the writer's own saving—which have been sown in especially marked pots for experiment—were attempted, the results have given less than 2 per cent of failures.

There are one or two points of interest which are not yet elucidated and any of your readers' comments would be welcomed. When saving seeds either from one's own crosses or from other varieties, it will be found that a full pod has the seed farthest away from the stem a different colour—brown instead of black. This seed is worthless and generally a dark brown plump seed of a black seeded variety is sterile. It does not, of course always occur at the end of the pod but often does so.

On chipping perfectly round seeds of some varieties, notably the orange or orange-red varieties and also Tea Rose, it will sometimes be found that the seed is green. It may germinate; the chances are that it will not, and in any case the growth will be bad. The author does not know how to avoid these imperfectly ripened seeds which he has also met in some numbers in the varieties mentioned, obtained from the best raisers; they have not, so far, appeared in other varieties.

On the other hand, some of the most miserable, shrivelled seeds, which no seedsman of repute would

A Beautiful Androsace.—A native of the Southern Alps, *Androsace helvetica* makes a very charming picture in the rock garden in July. A lover of sun, it should be planted rather high up on a steep slope so that—in combination with sandy soil and sharp drainage—there is no risk of it suffering from excess of wet, the greatest enemy that the Androsaces have. Make a note that it loves limestone and pound up a little of this for mixing with the soil. In appearance the plant forms dense little rosettes of leaves above which almost stemless flowers expand pure white with golden yellow throat larger than the rosettes from which they spring. Propagation is best effected in spring by careful division just when renewed growth is commencing, taking care to plant firmly and see that they are kept just damp until roots are working freely again. Established clumps that it is not proposed to divide benefit by top-dressing, both in spring and autumn, with a little fine soil dusted well in among the rosettes. The composition of this top-dressing should be finely crushed limestone and loam in equal parts.

ROBERT SYDENHAM LIMITED

NEXT week's issue will contain an account of the gardens at Harewood House, the residence of the Earl of Harewood, and presumably a future home of the Princess Mary.

Garden Economy.—As the articles which have been appearing on Garden Economy seem generally to have been welcomed, an effort will be made to continue them and even to enlarge their scope. An article in this week's issue on the very diverse varieties of the Polypody should be of interest to those who wish to carry on existing ranges of glass-houses with a minimum of labour and without fire-heat. There are many absolutely hardy Ferns which are highly decorative, while they retain their ornamental appearance much longer under glass. There is no reason, of course, to confine one's attention to Ferns. Flowering plants can be provided which will blossom over at any rate a large portion of the year even in our colder counties. Outdoors or in, true economy largely consists in the provision and use of the best and fittest tools; that is, fitted for their particular purpose. Where there is a large area of lawn mowing to be done, a motor mower is an immense labour saver. Then, too, there are many gardens where "to save mowing" many elaborate beds and paths have been provided which, aesthetically, could well be dispensed with. It is worthy of consideration, now, whether it would not be better and cheaper in every way to invest in a motor mower and at once save labour and improve the appearance of the garden.

Cheap Formality.—The formal garden has its advocates and its detractors. Many garden owners, however, with gardens laid out (as gardens of any size should be) partly on severely formal lines and partly quite informally, have latterly discovered that the formal garden is cheaper in upkeep than the informal one. If the beds in such a garden are arranged in turf, the actual cutting of the grass or edging of the turf is much easier and quicker than where the garden is laid out on curvilinear lines, while the planting of the beds with a line is proportionately simple. The more beautiful the curves in such cases, the greater the need for care in maintaining them; indeed, unless they can be maintained satisfactorily they should not be

employed, since upon their beauty of sweep the whole effect is dependent. The curves are not the only necessary parts of informal gardening, be it understood, but they are absolutely essential. The writer yields place to no one in admiration of good informal work, but he would point out that where strictest economy is a *sine qua non* this class of work should not be attempted.

The Rock Garden.—No unbiased gardener would consider this part of the garden cheap to maintain. To keep it in proper condition involves considerable expenditure of labour. Again, since among choice alpine losses inevitably occur, other plants must, from time to time, be purchased for replacement, or provision must be made by propagation to avoid this. Either course will

necessarily involve some considerable expense since, in the rock garden, many plants are accommodated in little space. No doubt many economists with no special love for alpines have dismantled their rockeries and allowed the easily grown rock plants in their dry walls to suffice. For those who have a real love for this form of gardening, and their name is legion, any sensible alteration to the rock garden is a bitter pill to swallow. It must be borne in mind, however, that nothing known to gardeners looks worse or is more "impossible" than a neglected and weed-grown rock garden. A sensible compromise in such case would, perhaps, be to maintain the moraine and some of the neighbouring cliffs for choice alpine, and to utilise the more distant banks for dwarf-growing American plants, such as Andromedas, Alpine Rhododendrons, Pernettyas and more particularly hardy Heaths. These are wonderfully effective and, the last named especially, to a great extent smother weeds.

The Kitchen Garden.—In this part of the domain efficiency, which is, of course, almost synonymous with economy, depends largely upon good organisation—this is vitally important in every department of gardening—and tools. Labour-saving appliances are many—every good tool may be considered so—but the importance of a first-rate (not necessarily expensive) grindstone, adequately mounted, needs emphasis. Where the garden is of some extent, some of the motor cultivators now in existence should make a big appeal, especially in these days of cheaper petrol. For smaller places (and for the larger ones, too, for finer work) some of the wheeled push-cultivators, such as the Planet Jr., are of great assistance. Where horse-power is available and not at present utilised to full advantage, the merits of a horse-cultivator should be weighed against those of the motor-driven ones. The latter have, however, a great advantage, as, being much shorter, they leave a much narrower headland. There are many grass orchards to private houses into which it is impossible to get a mowing machine owing to a few trees at each end being too near to the boundary. Arises, then, the question, if economy is the order of the day, whether, under the circumstances, these trees are worth their room.

AT ONCE ONE OF THE MOST DECORATIVE AND ONE OF THE EASIEST OF COOL GREENHOUSE PLANTS, PRIMULA MALACOIDES, NOW DISPLAYS ITS MANY TIERS OF DELICATE LILAC FLOWERS.

A NATURAL ROCK GARDEN

The story of a botanising and seed collecting expedition to Le Mont-Ventoux in Provence, with some account of the admirable reafforestation there, the remarkable geological formation, fruits, flowers and ferns, and a strange vegetable.

YEARS and years ago my French botanic friends told me that I ought to see the famous Mont-Ventoux in Provence. So I went two years ago, in the month of September, to Avignon. There I took, with a botanic friend, the motor 'bus leading to Carpentras, where we arrived for lunch—a sumptuous lunch such as they know how to do in that fertile part of fertile France, and how cheap! The land is covered with Vines, Fig, Jujube and Japanese Medlar trees and all manner of things good to eat. Then we took another motor 'bus and reached, soon after four o'clock, Bedoin, a big village at the foot of the Ventoux—Mons Ventosus of the Latins. Too late to make, that day, the ascent of the mountain, because we wished to make it on foot and not on the motor 'bus, we stayed there and did a little botanising in the neighbourhood. The peasants told us, when we admired the lovely fruits—Figs and Grapes: "Take whatever you like; everything is free to visitors. Take whatever you wish!" They would not accept a penny. This is typical of the generosity and greatness of Provence. In an hour's walk we had better luck than we could have imagined: Rosemary, Lavenders of two kinds (*Spica* and *delphinensis*), *Cistus salviafolius*, *Kentrophyllum lanatum*, *Asphodels*, *Aphyllanthes monspeliensis*, *Calycotome spinosa*, *Carlina acanthifolia*, *Salvia officinalis* and *Scalaria*, *Psoralea bituminosa*, *Thymus vulgaris*, *Armeria hupleuroides*, *Helichrysum stekas*, *Aster acris*, etc.; Corsican Pines, Cypresses, evergreen Oaks; while the beautiful *Eriobotryas* and Jujube trees adorned the country. Here and there, in some gardens, the evergreen *Lagerstrœmia indica* and the ideal *bleu celeste* *Ipomœa Learii* gave the brilliant note of the South, the dull Pines framing the whole.

There, up against the blue sky, the Mont-Ventoux shone like a glacier above the dark forests at its base. The glittering summit is a mass of glistening white stones, which the waters clean and polish thoroughly, year by year. We paid a visit to the head forester, who told us that the whole land was reafforested in the year 1861, as the Ventoux was at that date quite barren and unproductive, because of the devastations of past times, particularly when the monks waged war upon the Albigeois and the Valdesians, who were against Mass and the Pope. They burned the forests to seek for Protestants and, before that, for the Albigeois and Valdesians. So did they over the whole country, and hence comes the deafforestation of the Basses-Alpes, Vaucluse and Hautes-Alpes. But by that splendid reafforestation the local authorities have restored the whole of Mont-Ventoux on both the north and south sides. I was very astonished to find there quite a forest of Cedars of Lebanon (*Cedrus Libani*, or maybe some of them were *C. atlantica*). They seem to be quite at home here, and self-sown seedlings come up freely.

Early the following morning we started for the summit and took the superb road, built in 1882, which goes to the summit and is 6½ mds. wide and 22 kilometres long. In summer it is in constant use by motor cars and is perfectly maintained. We passed, first of all, some big Olive gardens where the Olive trees are well kept and

attended to, much better than in Italy. We now found beautiful Chestnut woods, valuable for their output of truffles. Then, at the eighth kilometre, we came upon and viewed with wonder the Cedar forest. The soil is covered with young trees and the slopes of the road are full of them. *Aster acris*, which is like a Galatella, flowers everywhere with the splendid "jone fleuri" (*Aphyllanthes* of Montpellier), while the truly beautiful and stately gold Thistle (*Carlina acanthifolia*) adorned the whole countryside. Its large inflorescence, sins, to rains, across, quite sessile, with its crown of silver *Acanthus*-like leaves, is the most brilliant ornament of the Provençal mountains. The people eat it as an Artichoke, and it is said to be more delicate than the Globe Artichokes, of which we are so fond. The rocks by the roadside are greened with *Asplenium Halleri* and other Ferns, particularly *Polypodium*.

At eight o'clock we reached the limit of the area reafforested (6,000 hectares). We enter now the real paradise for rock and alpine plants. All is lit up by the orange-yellow Pyrenean Poppy (*Papaver aurantiacum* or *pyrenaicum*), which flowers the whole summer until late in the season. As we are late, flowers are otherwise not to be seen. We came here for seeds, however, so that we are not too disappointed. But I ought to see the Ventoux in the month of June, said the botanists, when it is in its glory. Now, of course, there are only autumn flowers visible. But, see! *Androsace Vitaliana* flowering again and its large tufts of dwarf carpet cover the roadsides. We walk over it and the motors pass over it also. Some patches are a yard wide and are covered with seeds (or were, when it is already too late for them). The heads of the Blue Thistle of Provence (*Eryngium Spinallia*) are very curious with their silvery bluish stems and involucre, as finely divided as filigree. Not so finely cut, however, as the alpine one (*Eryngium alpinum*), but how picturesque and beautiful! It grows to 1ft. or 1½ft. high and has a stiff, very stiff, stem of a greyish blue colour. It seems stiff with pride and arrogance, being the one plant—the only one, which lifts its head above the ground. The winds here are so strong, so awfully formidable, that the vegetation is cut down and, like that of the desert, merely carpets the soil. Plants seek the protection of the stones and never can grow more than in. or zins. high. The Thistle alone stands out in the entire landscape.

We enter now the bare stretch of mountain at an altitude of 1,850ft., and at the tenth kilometre of the road everything seems at first sight to be dead. But, see! The desert is alive with the extraordinary vegetation of that curious mountain which is in itself quite a botanical garden. The whole top of the Ventoux we see now, white and glistening. The road cuts the slope and makes a dark line through it. We see the observatory at the summit glancing in the morning sun. And here, at the edge of the roadway, we find treasures and treasures for our collections. The carpets of *Douglasia* = *Androsace* = *Gregoria* = *Aretia Vitaliana* are so thick, so enormous, that we must walk upon them. The orange Poppy is everywhere and its beautiful cups of gold are alaze. Here is the strong scent of

Valeriana saluinca which forms, here and there, large tufts of yellowish-green foliage. Here are *Centranthus angustifolius*, *Campanula Allionii* (immense tufts of it), *Viola cenisia*, *Androsace villosa* (the last not so big as *Vitaliana*, but very widespread and large in size, too), *Iberis saxatilis* (in dense tufts, very compact and full of seeds) and *Dianthus subcaulis* (we came for this particularly) which is very common near the top and forms large, very dwarf and dense carpets. The plant is here dwarfer than in its other stations. Everything here, indeed, is very compact and hidden between protecting stones. At first sight one would fancy the summit of the Ventoux to be quite barren and destitute of life, but, on looking closer, one finds that "Lady Flora" has taken possession of every little corner of the ground and conceals in the fissures and in the crevices of every stone her treasures. The splendid *Androsaces* are surrounded with *Globularia nana* or *cordifolia*, *Teucrium Polium*, *Alyssum montanum* and *flexicaule*, *Iberis Candolleana* and *saxatilis*, *Paronychia* of two kinds, *Herniaria*, *Potentilla petiunculata*, *Ononis cenisia*, *Leuzea conifera*, *Saxifraga Aizoon* (of curious form), *S. oppositifolia* (with big flowers), *Athamanta cretensis*, *Æthionema saxatile*, *Anthyllis montana*, *Draba aizoides* and *tomentosa*, *Galium hypnoides*, *Ceterach officinarum*, *Scrophularia canina*, *Saxifraga moschata*, *Alsine baubini-orum*, *Villarsie*, *mucronata*, *grandiflora*, *tetraquetra*, *Senpervivum montanum* (a curious exception to the fact that this plant is calcifuge), *Silene Saxifraga*, *Oxytropis cyanea*, *Helianthemum polifolium* and *canum*, *Silene vallesia*, *Campanula pusilla* and *valdensis*, and *Phyteuma Charnelii*, which adorn the dazzling slopes.

The top (5,800ft. altitude) is occupied by the immense building of the observatory, which is in direct telephonic communication with the one at Paris. There is also a very good little hotel and some seats to rest upon and admire the unique scenery. From here may be seen the whole of Provence, the sea coast as far as Cete and the town of Marseilles shining in the sunlight. Yonder is Nimes and fairer Montpellier. The mountains of the Esterel and those of the Maures are to be seen to the east. To the north we see the whole alpine chain from the Maritime Alps to the Alps of the Dauphiné, the Barre des Ecrins, the Pelvoux, the Meije, and, above all these, the king, the beautiful Monte-Viso, my especial favourite, there in the far east. However, I was not there as an alpinist, and we went to the north side to find the rare *Aquilegia Reuteri*. From here we could go down to Malaçène by a beautiful way and a nice country, too, but we must by evening be back in Bedoin. So we started at midday by another route, going straight down through an immense field of Lavender and of Thyme and Sage. It was a real pleasure to go that way. The picturesque rocks, bared by wind and water—it is said that the winds there are as strong as those in the Sahara—the fields of *Aster acris* and of *Aphyllanthes*, all the treasures of the South disseminated over the declivities of the Ventoux gave us much enjoyment. I can but advise the amateur in search of beauty to visit that barren yet flower-decked summit where Flora has one of her most remarkable mansions.

Floaire, Geneva.

H. CORREYON.

THREE REMARKABLE CONIFERS

The three species described below all do best in our Western Counties, though the Taxodium is less exacting than the others.

THE HIMALAYAN HEMLOCK.—The genus *Tsuga* includes some of our most ornamental conifers, and of the seven or eight species which have been introduced into English gardens during the last century there is nothing to equal in beauty or elegance a well grown specimen of the Western Hemlock (*Tsuga Albertiana*), such as one sees in Scotland, where it often becomes a magnificent tree.

Its much rarer Himalayan cousin, *Tsuga Brunoniana*, introduced in 1838, is none the less interesting, but unfortunately, like most of the Himalayan conifers, it is apt to be injured by spring frosts and is consequently often seen only in a stunted condition, giving no idea of the size and beauty to which it attains in its native home. In Sikkim, for example, it commonly grows to a height of over 100ft. and is sometimes 28ft. in girth.

In this country it only becomes tree-like in such favoured localities as Cornwall and Ireland, where the climate suits it. The best specimen I know of is the one on Mr. Fortescue's estate at Boconnoc in Cornwall, where there is a tree measuring over 50ft. high by 12ft. in girth near the ground. Here it branches into several stems which spread to about 70ft. in diameter. Young plants have been raised from cones produced by this tree.

The only tree of any size near London appears to be the one at Dropmore, which was planted in

1847, but is not so fine a specimen as that just mentioned. The branch illustrated on this page was taken from a well developed tree in Sir Archibald Lamb's collection at Beaufort, Sussex. When recently measured by my friend, the Rev. A. E. Gregor, it was about 35ft. high and 4½ft. in girth of stem. I have notes of other examples at Menabilly and Tregrehan in Cornwall, Leith Hill, Surrey; while in Ireland there is a notable tree 40ft. high and about 5ft. in girth on Lord Barrymore's estate at Fota, Co. Cork, and other smaller ones at Kilmacurragh and Powerscourt in Co. Wicklow.

The illustration (from a photograph by Miss Brown) shows well the long narrow tapering leaves which at once separate this Hemlock from the American and Japanese members of the genus.

THE DECIDUOUS CYPRESS.—Few foliage trees can compare in beauty with the Deciduous Cypress, botanically known as *Taxodium distichum*. It is an elegant tree with feathery leafage and one to be greatly valued for its light green effect in spring and summer, while in autumn its yellow and light brown leaves form a touch of good colour, which contrasts pleasantly with any foliage retaining the green of summer.

Taxodium distichum has the conical shape of a Cypress, but unlike all other conifers, except the Larch and the Maidenhair Tree (*Giukgo biloba*), it is deciduous. On account of these distinctive characteristics it has gained its name of the Deciduous Cypress.

During the dull season the *Taxodium* is not without charm as some might suppose it to be, for its straight central stem and lacery of shapely leafless branches constitute a tree of unique appearance.

The Deciduous Cypress is a native of the Southern United States. It is naturally a great lover of moisture, and is consequently usually seen in association with streams, ponds, or lakes. Sometimes it will be growing in water a foot or 18ins. deep, but more often in the adjacent marshes.

For riverside gardens, as well as for beautifying small islands in ornamental waters, it is invaluable, and it can be relied upon to give character to the scene.

A marsh is not essential to its well being provided that it is given a moderate supply of water in dry weather, and good specimens are often to be seen on lawns. In order, however, that it should get sufficient moisture, it is desirable

to select for it a low-lying situation rather than one on a high level; unless the latter, as is seldom the case, happens to be a moist one. The artistic character of the foliage is better appreciated if the *Taxodium* is grown in conjunction with some plant with large leaves such as the Gunneras, or the broad-leaved Bamboos, which contrast well with the fine feathery leafage.

The Deciduous Cypress likes a deep loamy soil, and can be planted in early spring, winter, or as

A SPRAY OF *TSUGA BRUNONIANA*.

THE REMARKABLE RESIN-LADEN CONE OF *ABIES BRACTEATA*.

soon as the leaves have fallen. After planting it requires no pruning or attention at all, unless it be occasional watering. It is, therefore, a tree very naturally adapted to the wild garden.

ABIES BRACTEATA.—Discovered over eighty years ago in the Santa Lucia mountains of California and introduced by William Lobb when he was collecting for Messrs. Veitch in 1853, this remarkable Silver Fir is still one of the rarest of its kind. Unfortunately, it has not proved suitable for the British Isles generally and appears to thrive only where the conditions are soft and warm. Nearly all the best specimens are to be found in the gardens of the West Country, such as those of Eastnor Castle, Totworth and Highnam Court. In these places there are trees of 65ft. to 80ft. high. *Abies bracteata*, the Santa Lucia Fir, is the most distinct of all Silver Firs, being well marked from all the rest by three characters, viz., its elongated, sharply pointed, pale green winter buds; its long, rigid, spine-tipped (never notched) leaves; and its remarkable cones, one of which we illustrate. These, as will be seen, are armed with long, stiff spines as sharply pointed as needles, each of which is a prolongation of the bract. The whitish clusters seen attached to many of them in the picture are patches of resin.

Three coniferous trees more distinct and remarkable than those mentioned would not be easy to find, nor three more beautiful.

SOME VARIETIES OF THE COMMON POLYPODY

Many readers are anxious to know what they can grow to furnish an absolutely cold house. As hardy as the proverbial nail, the many varieties of *Polypodium vulgare* supply, at any rate, a partial answer.

ACTING on the principle that a good illustration is more directly informative than descriptive text, no matter how good the latter may be, we illustrate herewith some of the best and most distinct forms of the common Polypody (*Polypodium vulgare*) which, while of necessity having to play second fiddle to the "Hart's Tongue" from the numerical standpoint, is second to no hardy Fern from the standpoints of real hardiness, extreme beauty and simple cultural needs. The varieties are also evergreen and, endowed, amid suitable environment, with considerable powers of endurance, afford us not a little of their best garniture till near the end of the year. With cold house treatment—a method of cultivation calculated to display them to the fullest advantage—their season of leaf beauty is considerably prolonged and one never tires of the opportunity of seeing the best of them at close quarters and marking the changes as these occur.

Both in leaf colour and beauty the Polypodies occupy a place of their own. There is, for example, none of the lustrous green so characteristic of the Hart's Tongue or the russet-brown which distinguishes the *Polystichum*; but in place of these a pale or middle-green tone, difficult to describe, yet ever beautiful and attractive, with just those finishing nature touches which, while intended probably to compensate for the absence of flowers in these plants, also afford variety and create interest.

Turning to the varieties figured in the illustration, we have in those marked one and six the two extremes of the group as at present known; the former the original or typical kind, the latter the most finely plumose of the whole series. Between

these two extremes there are many varieties, some of irresistible beauty and all of interest. Of the latter the student is afforded food for thought by the varieties of *grandiceps*—numbers four and eight respectively—which, entirely bereft of their pinnae and with modified rachis or midrib, have nothing in common with the normal type. Most amateurs would, however, turn instinctively to the more decorative of the set—those which, like the variety *pulcherrimum*, have assumed a wider lateral frond spread, or those others as, for example, *cambricum*, *c. Barrowi* and *c. Prestoni* which, having developed laterally, have also assumed a density and plumosity which render them ornamental in the highest degree. These densely plumose forms have affinity with *cambricum* (the Welsh Polypody), itself one of the handsomest of the race. The variety *trichomanoides*, with its very suggestive name, has the most finely divided fronds of all, and while not of the moss-like density of some of the modern *Nephrolepis*, may yet break into something near akin. Its present state is well shown in the illustration. Its nearest approach is the variety *elegantissimum*—not shown in the figure—a plant rather difficult to obtain true. The fronds are of flatter form than the last, less dense in character, the plant far more vigorous. The true plant is well figured in "Nicholson's Dictionary of Gardening," page 195. There are others, such as *omnilacerum*, *semilacerum*, *cambricum plumosum* *Hadwini*, making up altogether some thirty or more sorts, all of which possess interest or beauty.

All are rhizomatous, that is, they possess running root stocks or stems clothed with ferruginous scales, and are easily cultivated in loam and

limestone chippings or peaty loam. The typical kind is often seen in dry hedgerows struggling for existence, while frequent in woods at the base of trees and again in walls, from which it will be seen that it is not fastidious. Magnesian limestone chippings with strong loam are ideal for *cambricum*, and that excellent variety, so treated, flourishes in a cold house.

For the opportunity of figuring the varieties in the accompanying illustration we are indebted to Messrs. H. B. May and Sons, Dyson's Lane, Edmonton.

Herbaceous Plants that Flower Early

HERBACEOUS plants that have not begun to flower by the beginning of June can scarce claim a place in these brief notes, which are to deal with those plants that bloom early. On the other hand, there are herbaceous plants that give us of their flowers so early as to be classed by some writers as spring flowers. The convenience of this distinction may be allowed and is apparent. I think, when calling to mind such things as the Lungwort, *Pulmonaria mollis*, which is in full flower by the middle of March; *Anemone sylvestris* and *A. Pulsatilla*; *Aquilegia* of sorts; and the beautiful *Dicentra spectabilis*, which, unless sheltered, is sometimes spoilt by spring frost. However, leaving these on one side, we have a fine array from which to make an early flowering selection.

Though common enough, the Leopard's Bane (*Doronicum*) is very useful. It is a composite, bearing yellow single, *Chrysanthemum*-like flowers. Towards the end of April the first buds of the Mountain Globe Flower, *Trollius europæus*, are almost ready to open. In April, too, one or two of the Yarrows should make a start, particularly the form of the common Yarrow, *Achillea Millefolium*, for example. The month of May ushers in the European *Paonies*, which, in turn, are followed by the Chinese kinds. Where space is limited and only a few plants can be grown the *Paony* ought certainly be one, for, as a writer has well put it, "What is even a cottage garden worth without its rich red *Pyannies*?" Opening also in May is that splendid hardy plant the *Pyrethrum*, which few plants can beat for freedom of flowering, brightness and usefulness. Like the *Paony*, the *Pyrethrum* is quite hardy. Both bear single and double flowers of great decorative worth, whether in the border or indoors as cut flowers. The good qualities of these two plants are also shared by the *Lupin*, of which mention was made a few weeks back.

An old plant not so frequently seen as the foregoing is *Jacob's Ladder*, *Polemonium coruleum*. It is well worth growing where early flowers are appreciated. There is also a useful white variety. Of bushy habit, few plants are more useful for early work than the indigenous *Musk Mallow*, *Malva moschata*. It grows and flowers freely in most soils. Several of the forms of *Chrysanthemum maximum* are ready in June, while *Chrysanthemum latifolium hybridum* may sometimes show itself towards the end of May. Other plants worthy of mention are the gorgeous blue *Alkanets* (*Anchusa*), *Gaillardias* and *Galega*. Some of the beautiful varieties of *Anchusa italica*, such as, for instance, *Dropmore Variety* and *Opal*, are grown in most gardens; but the early and ever-blooming *A. myosotidiflora*, which only grows a foot or so tall, is not so often seen. It is a wonderfully easy and excellent plant. Nor must the brilliant *Oriental Poppies* be forgotten.

THE COMMON POLYPODY (*POLYPODIUM VULGARE*) AND SOME VARIETIES.

- 1, The typical plant; 2, *cambricum Prestoni*; 3, *pulcherrimum*; 4, *grandiceps Parkeri*;
- 5, *cambricum Barrowi*; 6, *trichomanoides*; 7, *cambricum*; 8, *grandiceps multifidum*,
- 9, *cristatum*; 10, *cornubiense*.

With immense variety of habit and an equal diversity of colouring, they are quite indispensable in the early summer border. Pure white, salmon-pink, rose, orange, crimson and quaint smoky tones are all represented, with numbers of intermediate shades. When well grown the Iceland

Poppies too (*P. nudicaule*), are invaluable at this season. They are excellent for cut flower. Another plant which should be included is the perennial Pea, *Lathyrus Sibthorpii*. It grows to a height of about 3ft. and bears dull red flowers in great profusion. C. T.

tained and plenty of atmospheric moisture provided. The plants should be fed with weak liquid manure from the time the first flowers open, for the pots will be crammed with roots, which soon become starved unless treated generously. A temperature of 50° to 55° is ample both for sowing the seeds and growing the plants. H. W. CANNING-WRIGHT.

BLACK-EYED SUSAN

All about a very useful and beautiful annual for the greenhouse or sheltered corner outdoors.

WHERE a restrained grower is needed in a small greenhouse to twine round a thin wire or for very sheltered positions in the open garden against a south wall

the annual Black-Eyed Susan, *Thunbergia alata*, is an ideal plant, the seeds of which can be sown any time from the middle of February to April. The flowers are either white, buff or tawny orange, and each has a dense velvety black eye, forming a striking contrast to the ground colour. Occasionally one meets with self-coloured plants, and very attractive these are, especially the pure white form. A light open soil should be used for sowing the seeds, using small pots and placing a couple of seeds in each pot at the centre. Stand these in a warm position in the greenhouse over the boiler being good, so as to induce rapid germination. The seeds are rather hard, but must not be overwatered or they readily decay, though the soil must not become dust dry. Cover with about half an inch of earth. If sown too shallowly the young plants are apt to push through with the seed case attached to the cotyledons. This toughens and so inhibits further growth of the plant. Should both seeds germinate, one plant should be drawn, and this is best done at a fairly early age or the roots become intertwined and when one is pulled they both come out together. When they begin to climb give them something to cling to, and before they become pot-bound transfer to 5in pots. These are large enough for single plants that are to be trained over a division wall or run straight up to the roof by a wire. Most decorative plants can be obtained by potting up three small plants in the 7in size pot and placing a stake in the centre about 4ft tall. A wire should then be run round the rim of the pot and four or five strands of tarred twine

from this to the apex of the stake. The growths need watching and encouraging to "take," but when once started will run away freely and support themselves. From the end of June onwards wonderful pyramids of flower are attained blossom-

THE UNCOMMON PURE WHITE FORM OF THUNBERGIA ALATA.

ing from base to tip, that remain decorative right into September. One pest alone in my experience is likely to prove troublesome—thrips—and these can be circumvented by occasional fumigations and free syringings with an insecticide. Usually thrips do not prove unduly tiresome. They are most prevalent in hot weather, so that a uniform temperature should, as far as possible, be main-

tained and plenty of atmospheric moisture provided. The plants should be fed with weak liquid manure from the time the first flowers open, for the pots will be crammed with roots, which soon become starved unless treated generously. A temperature of 50° to 55° is ample both for sowing the seeds and growing the plants. H. W. CANNING-WRIGHT.

CAPE PRIMROSES

These plants are invaluable for the cool and somewhat shady greenhouse. They succeed even under staging.

NONE will deny the extreme beauty and daintiness of the Cape Primrose, as the *Streptocarpus* is sometimes called. They are among the most useful of greenhouse plants since they commence to bloom early in May and continue without cessation until November. Raising from seed is an interesting process, for an immense variety of shades, colours and markings result. Seed is extremely fine and requires careful handling until the small plants are some size, and progress is rather slow at first.

Drain the pots to about half their depth with small crocks, covering these with a layer of moss; then fill to within half an inch of the rim with sifted compost, one part of loam, one of peat (finely crumbled), and one of silver sand. Make the surface perfectly level, and water through a fine-rosed can. If boiling water be used it will destroy any insect pests there may be in the soil. Time should be allowed for the soil to drain and cool; then open the packet and thinly scatter the seed on the surface only. It is unnecessary to cover save with a little fine silver sand.

Put a pane of glass over the pan, covered with a sheet of thin brown paper, and place in a temperature of 60° or so. They will not require water for some time, but the glass should be turned daily, or the condensation wiped from it. When water is needed it should be given by standing nearly to the rim in tepid water and allowing it to percolate upwards. Immediately they germinate the paper covering should be removed, though sunlight must not be allowed to reach them. Keep them growing on as rapidly as possible and directly they can be handled they should be pricked out in seed pans zins, apart. Do not delay this; get them pricked off at the earliest possible moment, and, again, as soon as the leaves approach touching each other, pot singly into thumb pots, using a compost of two parts fibrous loam to one of peat or leaf-mould, preferably peat, and a good dash of coarse sand. Water should be given in moderate quantities until they begin to grow again, then a fairly free supply, taking care, however, that none is spilled on the foliage. Continue to shift until the 5in. size is attained, which is plenty large enough for them to flower in. Once the pots are well filled with roots, diluted liquid manure may be given, twice a week. At each potting look well to the drainage.

Streptocarpus are shallow rooting and depth of soil is only harmful, as it may sour. Old plants can be increased by division in early spring. During winter only enough water must be given to prevent drooping of the leaves. They are not at all particular as to temperature, doing in summer quite as well as when only kept free of frost during winter, or when grown in the stove, save that they commence to bloom at a much earlier time in the higher temperature. By growing on different batches they will provide a

continuous succession right through the year. Cultural treatment of old plants merely consists in giving plenty of water and shading from sunlight; they prefer rather heavy shade and a moist, humid atmosphere, always taking care that no moisture rests on the leaves. Huge specimens can be grown by potting on without dividing.

The mixed hybrids provide plants of very neat habit, 6 ins. high, and a great abundance of

trumpet-shaped blooms—pink, mauve, white, purple and blue of all shades. *S. Wendlandii* is curious but not of great value as a flowering plant. It makes one immense leaf and a tall spike of rather small flowers, remaining in perfection for a very long time. There are now quite a number of named kinds in all colours, of immense size and very perfect in form.

A CAMPANULA GARDEN

Large areas of the garden (and THE GARDEN) are devoted to Rose and Iris gardens. Why not spare a little corner for the many beautiful Campanulas?

DURING the latter half of June and through July one of the predominant hardy plants is the Campanula, and an ideal little piece of planting can be arranged by grouping a number of the choicest species of these together, so as to form a small Campanula garden. Nor is there the least risk of this appearing monotonous either in stature, colour range or form, for there is so much beauty and diversity that—in the planning—it is far more trouble to eliminate than to select.

Canterbury Bells, of course, should occupy a good amount of space; these are invaluable for massing especially as by cutting off all the dead blooms as

they fade every plant flowers twice. This is true of most of the upright growers, including the essential *C. persicifolia* and *C. pyramidalis*. The latter is one of the grandest border forms, in addition to being fine in pots, though it is so popular in the conservatory that we are sometimes in danger of forgetting that it can be grown entirely in the open. Towering up to 5ft., it is one of the most commanding varieties of all and should be grouped in outstanding positions.

In the *persicifolia* varieties there are so many fine forms that the type plant is no longer worth growing. *Persicifolia alba grandiflora* is the largest and best white I have seen to date, and no garden is complete without it. *Moecheimi* is splendid for cutting and bears its solid semi-double white flowers with great freedom. The variety *humosa* is another, indispensable for its soft blue shade. It has rapidly become very popular both for the garden and as a pot plant.

Latiloba should not be omitted, for the closely arranged spikes are very showy and do exceptionally well on shaded borders where the 3ft. stems are grand for weeks together. It is in the dwarf varieties that the great charm of the Campanula garden lies, however, for we can pack such an immense number of *chic* and charming little flowers into a small area. Contrary to popular belief, a rock garden is not essential for huge numbers of these. They grow just as freely and easily on the level in great spreading clumps as among stones. Of course, for a few crevice lovers—and those impatient of wet—rocks are essential, but all those I am about to mention will flourish on the level. *Carpatica*, especially the varieties *Isabel* and *White Star*, the former deep blue, the latter pure white, flowers for three months if in a cool position, but it goes out in one great short-lived blaze of glory in hot sunshine. A variety

of this, that is very well worth noting where a plant about 6 ins. high is required, is *carpatica* Little Gem, pure chalk white.

C. caespitosa—of similar habit to *pusilla* and therefore spreading rapidly—makes splendid edgings to beds of the Cup and Saucer Canterbury Bells, the light green foliage and soft blue flowers harmonising excellently with their varied colourings.

C. garganica I find absolutely reliable and hardy, doing well on the level, the crinkled leaves and five-starred tiny flowers making it a most welcome and distinct addition to the prostrate growers. It must have full sun, and this note is especially applicable to the hairy *garganica hirsuta alba*. Given sandy soil and full sun, nothing excels *C. muralis* for edging purposes, for it so covers itself with deep purple bells that one loses sight of the fact that it has any foliage until those bells have faded. From July until the middle of August you have an even band of dense evergreen foliage; then a second crop of buds makes its appearance and—in September—the edge is again smothered with deep purple.

C. nitida is another plant, reaching a height of 6 ins. with whorls of erect stemmed flat blue flowers over dark shining green foliage. Good patches of this are useful next to *C. garganica* as—just as the starry flowers of this are passing—*nitida* commences to bloom and continues into September. *Pusilla* is ubiquitous and should be allowed to run wild in the Campanula garden, for it has a knack of placing itself far more happily than our studied efforts can achieve.

Running between steps, establishing itself in small tufts at the edge of paths or spreading itself in between the clumps of taller growers, where it forms a carpet beneath their handsome spikes—these are some of the ways in which *pusilla* inserts itself into our affectionate regard. Unless absolutely impossible to allow it to remain, few have the heart to root up the dainty little slender-stemmed bell-covered plants wherever they choose to appear.

Do not overlook the charm of our own native Harebell, wilding though it be, for it is one of the most elusively beautiful of all—especially the double form and the exquisite white one. This, like *pusilla*, appropriates as much of the garden for its seedling offspring and has just the same happy knack of fitting itself into just the correct surroundings.

(CROYDONIA.)

WONDERFULLY EFFECTIVE, ESPECIALLY WHEN MASSED—
CAMPANULA CARPATICA.

THE BEAUTIFUL WAX FLOWER

Beautiful by name and nature, this plant is, when in blossom, deliciously fragrant.

THE popular Wax Flower, *Hoya carnosa* from Canton, is one of the warm greenhouse plants most frequently met with, and it certainly is very splendid where a good space of wall, covered with netting, can be devoted to it. *Hoya bella* is, however, an entirely different plant, and it is only occasionally that one comes across it. Unlike *H. carnosa*, it is upright and shrubby in habit, with small, oval glossy leaves. It is short jointed and branches freely. The flowers are pure white with a tiny chocolate red star and anthers at the centre. They are tremendously fragrant, a small plant being sufficient to make heavy with perfume the air of a moderate sized house. The heads of bloom are freely produced and remain a considerable time in perfection.

Additional plants are easily propagated by cuttings taken either in early autumn or spring. Young plants rooted in March frequently flower during summer. It appears to the best advantage when suspended from the roof, either in pots or wire baskets lined with moss. Several young plants should be placed in each. Free drainage

A PLANT OF HOYA BELLA, THE GROWTHS TIED UP TO DISPLAY THE FRAGRANT BLOSSOMS.

is essential, for they do not make much root, and a compost of fibrous loam and coarse sand with a little peat is best. Break the loam and peat into small lumps, add the sand, and pack closely into the pots or baskets, avoiding pressing down hard. The Hoyas like a lumpy soil that does not run closely together, and while keeping uniformly moist, never overwater, as they easily become sickly if an excess is applied. During winter very moderate supplies only are necessary, allowing the soil to become almost dry before giving more. A temperature of between 50° and 60° should be maintained.

If one has only an ordinary greenhouse temperature one may still grow it quite as successfully, but flowering will be a little later, and cuttings should be struck correspondingly later. It will be noticed when cuttings are detached from the parent a white milky juice begins to exude from the stem. They should be laid on the greenhouse shelf for twenty-four hours to callus before insertion, as this reduces the risk of their damping off. W.

MY "GENTLEMAN GARDENER"

The following appreciation is worth careful reading as a contribution to the labour difficulty of which we hear so much to-day.

THE fact that I am happily circumstanced in respect of my one and only gardener has moved me to write this appreciation of a worker who is at once a credit to his calling and a continual refreshment to his employer. Am I not justified in believing that this is a theme worthy of attention, even if it be one not before treated in the pages of THE GARDEN? From time to time we read of illustrious gardeners, but here I seek to tell of a very humble person, just one of the rank and file, who doubtless has his counterpart in many another garden, to the abiding comfort of his master or mistress.

During the war I rightly lost my John Allison for a time and was reduced to availing myself of the services of a Trade Unionist of the undesirable type. This individual, like many other Socialistic workmen, passed his days in a state of continual discontent. Miserable and disgruntled himself, he made the garden a place of discord and drove far away the peace which rightly dwells in the flower patch of a man's home. Under his clumsy hands vegetables certainly flourished, but flowers, which are the very soul of the garden, declined, while the choicer varieties wilted right away. Pests unknown before assailed the greenhouse plants. Cobwebs invaded the Carnations, Chrysanthemums sported positive whiskers of rust and Orchids became fastnesses for scale and mealy bug. All this was distressful enough, but when coupled with steady sourness on the part of the alleged gardener it became intolerable. "The garment of praise" was snatched away from the garden, and in place there settled upon it "the spirit of heaviness." Finally, my Bolshevik jumped into a "funk hole" to escape conscription, and for a time we went further down hill horticulturally, while well meaning but incompetent females scratched the surface of the ground in the vain endeavour to carry on.

And then came a joyful day when my soldier returned—returned with all the old skill and keenness, and with fresh store of patience learnt in the hard school of war. After the "grouser," the gentleman; the change of atmosphere was amazing. Of a truth there is no valid reason why there should not be "very perfect gentle" gardeners, even as there have been knights of the same high degree. "Manners mayketh man," be he warrior in steel or khaki, or labouring man armed with no more lethal weapon than a spade. It is not the station in life, but the instinct; not the breeding, but the spirit, which in the true sense produces that delightful being, the gentleman or the gentlewoman.

With this prelude, let me proceed with the appreciation of a servant and friend. To begin with, Allison loves his work; above all, he loves his flowers. When any new or specially gracious bloom appears I have known him snatch many precious moments of a strenuous day just to feast his eyes upon the glad sight, and thereafter to "return like a giant refreshed" to his labours. The first openings of *Gentiana verna*, of *Saxifraga Irvingii*, of *Carnation Lady Nunburnholme*, of *Sophrontis grandiflora* might be instanced, but why expand the list? Every flower-lover experiences like thrills, yet I doubt few paid gardeners are fortunate enough to know and gratify them. Of the average garden worker it may honestly be said:

"A Primrose by the river's brim,
A yellow Primrose was to him,
And it was nothing more."

But the "yellow Primrose" merchant will never capture the real privileges of the craft which he follows, nor is it likely that his master will find himself moved to sing his praises in print.

After the blighting effects of the Bolshevik régime, Allison was faced with an almost overwhelming task. It was not enough to destroy much of the under-glass stock, but the very houses had to be purified. Not enough to remove the weeds from the rock garden and buy new alpines, but the rocks themselves must be unseated to eradicate evil roots which had gone deep to earth with intent to ramp at large in years to come. Of small avail to lift the herbaceous stuff, so weakened was it by seasons of unchecked growth and the overrunning of neighbouring plants. None the less, my stalwart has brought the garden back to its former order and beauty; indeed, like Job of old, I am "blessed more in the latter end than in the beginning." It has been a work of love even more than one of duty, and love, we know, "never faileth."

A while back a branch of the Gardeners' Trade Union—I forget the exact title—was started in this little town, and to the meeting which inaugurated its establishment Allison was invited. A flamboyant handbill was sent out, promising high wages, overtime pay and prolonged holidays. After the meeting I asked my helper whether he had attended.

"No, sir," he replied, "I am satisfied as I am; you and I can arrange things together well enough without any Union."

True words these, words which one would look to hear from the lips of a man who loves his work and has no intention of submitting to outside dictation as to hours or rules of employment upon it. Trade Unions have rendered excellent service to labour in the past. Far be it from me to decry them, but they surely step outside their province when they push into the home and seek to bind those who serve there down to regulations only applicable to commercial undertakings. If a man is happy in the garden, if he knows that his plants often need him early in the morning or late at night, why in heaven's name should he be compelled to "knock off" at a set hour and thereafter spend his time in less congenial occupation?

I wander away from my text somewhat, although the subject is a vital one to readers of this paper. Let me tell now of the past strenuous summer when the unexampled drought brought in its train such scourges as white fly and red spider in hordes like the sand of the seashore in multitude. By cyaniding, Allison slew all greenhouse invaders save the "spider," which paid no regard even to this deadliest of poisons. After taking such an extreme step the ordinary gardener might well be excused for folding his hands and murmuring "Kismet." Not so the man of whom I write. Early and late he has toiled among his Carnations, syringing them by the hundred with water and sulphide of potassium until at last he has exorcised the evil host and cleared his plants of that which was sapping their very vitals. This is but one instance of devotion to his charge. Doubtless many other gardeners have done precisely the same things, but in the catalogue of my friend's excellences I am entitled to set down the fact that he overcame a murrain of red spider, which, to my certain knowledge, is to-day in firm possession of some of the most celebrated nurseries of Carnation growers.

This incident, it may be urged, has small bearing upon the "gentleman" side of him of whom I

VEGETABLE DOINGS

Seed Potatoes: their Care at this Season

tell, but gentlemen were ever good fighters, whether with dragons of old or with evil "bugges" of later spawning. At any rate, I can put to Allison's credit the personal peril of his experiments with cyanide and the cheerful spirit with which he took up the war with new weapons when even poison gas failed.

Recently I had an experience at home which finds no parallel among the considerable number of hands employed in my city works. It happened upon a pay day when Allison remarked: "You had better reduce my wages now food has dropped in price." I had not even hinted that the gardener's pay should follow the Index Figure downwards, so that the man's offer was particularly pleasing and in keeping with his fine spirit. As I recalled the violent opposition to wage reductions put up by the various Unions with which I come into contact, notwithstanding the heavy fall in the cost of living, the thought obtruded itself—what a different thing business would be if Labour occasionally volunteered like suggestions! Bitterness between employers and employed would be impossible were this give-and-take disposition manifested by operatives, and industry lifted on to a happier plane altogether.

There is a personal side about Allison which strongly appeals to one. Self-respecting to a high degree, he is as neat in his dress as in his work. The man's hands are a pleasure to behold. They are those of the artist rather than of the artisan; well fitted for delicate layering and grafting, and yet strong for heavy labour with spade and axe. My friend is a great reader, especially of any literature relating to horticulture; while he is almost a chemist in the skill and knowledge with which he compounds his various soils and manures.

Probably no relation between master and servant is closer than that which exists between the garden owner and the gardener, provided that both love the plants which they grow. They have a huge hobby in common and that supplies a tie which years do but knit the firmer. I am happy in Allison and I verily believe that he is happy in me. We mutually encourage each other in the dear interest of flowers and we both enjoy our small triumphs the more keenly because we enjoy them together. Surely this is just as it should be, as it cannot fail to be with everyone who is fortunate enough to possess a "gentleman gardener." D. N.

The Cinderella of the Gold Dust Family

A rock plant which is not too common, yet is not really scarce, is *Alyssum spinosum*. It is quite hardy and not at all difficult to grow in sandy soil. It is not particularly effective in the early stage of growth, but once it has attained 1ft or more across is very attractive. It is pretty even when out of bloom, as it forms a mass of silvery grey foliage, studded in summer with heads of small white flowers. There is also a variety with pinkish or rosy flowers (*spinosum roseum*), but these are not pronounced enough in colouring to please the average gardener. This tendency to colour may, however, be valuable, as a variety with deeper coloured blooms would be valuable. It is not easy from a young specimen to understand why the specific name of *spinosum* is applied to the plant, but the name is seen to have a good foundation when the spines which are on the lower parts of the branches are once observed. Good plants will grow to more than 2ft. across. *A. spinosum* is increased by seeds or cuttings. A sunny position seems best to suit this neat and pleasing rock plant.

ALL cultivators should make a very close examination of their stocks of seed tubers forthwith, so that they may have them in the best possible condition at planting time. This examination should not be put off till that time actually comes. Expert cultivators are never guilty of such neglect.

WHAT TO DO AND WHAT NOT TO DO WITH SEED POTATOES.

The winter season has not been a difficult one as regards the storing of seed tubers without recourse to heavy coverings to exclude frost. On the other hand, even light coverings, if left on unduly, would result in weakly unsuitable sprouts. I knew, personally, the late Mr. James Clarke, the raiser of *Magnum Bonum* and other noted varieties. It was a valuable object lesson to inspect his stores of seed tubers in boxes in the depth of winter, since he paid as much attention to his Potatoes in winter as in summer time.

He rarely had to remove any sprouts just before the planting season as ample exposure to light and air resulted in just sufficient sturdy blue-black shoots on the tubers after the removal of weakly ones before Christmas.

Cultivators who have their seed tubers, whether covered or not, in shallow boxes, should lose no time in setting them out in single, or at most, double layers and fully expose them to the light and air where there is not any frost. I know the majority treat the early kidney sorts in this way, but I find it pays to treat second early and maincrop varieties in the same manner.

It is probable that fewer tubers will need cutting this spring than in former years owing to the great number of undersized ware Potatoes. Judging from other growers' experience as well as my own, I find seed tubers of the kidney type, about 3 ozs. in weight, to be the best, and of the maincrop varieties half an ounce heavier to be an equally suitable weight.

The accompanying sketches will be helpful to the inexperienced grower. No. 1 shows a kidney or early "set" as it should be when planted. No. 2 shows a maincrop "set" as it will be, probably at the present time. It will be time well spent if these are overhauled and all sprouts rubbed off except two that are best placed. If large tubers are to be cut they should be dealt with as shown at No. 3, being divided at the straight dark line and the cut portions dusted over with powdered charcoal. If 1lb. of seed of a new variety is to be made to go a long way treat the "eyes" as shown at No. 4. No. 5 shows the kind of sprout to retain and No. 6 the kind to discard. GEORGE GARNER.

The Increasingly Popular Swede

It is very surprising to find how many people are growing the humble garden Swede who despised it so thoroughly until a few years ago. Up to 1917 the Swede was regarded as a crop only fit for farm culture, but the fact that its food value rendered it a good substitute for Potatoes during the severe Potato shortage has brought it into favour with many people. Many gardeners, however, do not get the success that they might on account of sowing it too late. One expert recommended northern gardeners not to sow Swedes until June, and when this was tried it was found that the Swedes grew to no size at all.

My own experience with Swede growing has been that the earlier the seed is got into the ground the better. Sowings in March give splendid results, and April sowings also give fair returns. I have never found Swedes to run to seed, and this makes them suitable on ground where Turnips will not stand for more than a week or so without becoming uneatable.

More importance should, I think, be paid to thin sowing. Large Swedes are, of course, perfectly permissible, for the larger they grow the better they are, but if each plant has to jostle with seven or eight neighbours the resulting roots are poor and coarse. Eighteen inches between the drills and 12ins. between the plants is the absolute minimum, but when sowing it is possible to get some useful material for the stewpot if seed is sown three or four together at intervals of 3ins. It is needless to say that Swedes should not be sown on ground infected with club-root. If this must be tried, lime and salt should some time previously be incorporated in the infected soil. YORKSHIRE.

CORRESPONDENCE

SPORTS AMONG WILD ORCHISES.

I QUITE agree with what is stated in your article on "Mendelism Vindicated," that the loss of the purple colour in our wild Orchises usually coincides with losing vigour in the plant. Near here there are fields full of the Green-Wing Orchis, which I have visited every year for the last forty years to hunt for the few pale pink and pure white forms to be found among the deep purple ones, and I have never once found these pale forms as large as the purple ones. In July last the late Mr. George Paul showed me a fine hybrid between our wild spotted Orchis and the Madeira ones. They had the vigour of the Madeira and the hardy constitution of our native ones. He wanted to cross these hybrids again with our spotted ones and I got him some specimens from Suffolk, the largest I had ever seen, but the work ended with him.—H. H. WARNER, *Hoddesdon, Herts.*

FROM AN OREGON READER.

I AM mailing you some photographs of our garden which you might possibly care to reproduce at some time. I have never made

any notes on gardening that would be of much interest to others. As you will see by the photographs, we have a natural background of tall, very old Douglas Fir trees with some native shrubbery and varieties not native. We have planted our perennial borders in front of this background. We have planned and worked out the garden ourselves, a little at a time. There are grass paths everywhere, and in the rose garden the beds are bordered with Violas. We have about three acres of woods, some of tall Douglas Firs and some second growth, with Dogwood, Maple and Arrowwood, and are just beginning to develop them. We have naturalised the common English Primrose and have Daffodils, Scillas, etc., scattered in groups through the woods. Our climate here, in the north-west, is similar to the English climate, and your paper is much more

which I suppose is different from the English summer.—JANE MONTAGUE, *Portland, Oregon, U.S.A.*

SOME NEW ROSES?

I THOUGHT the enclosed (local) auctioneers' announcement might amuse you. If you can tell me what the first Rose in the standards is supposed to be I shall have a still greater admiration for your efforts than ever! I think "Worthy Perkins" is indeed a "choice and rare" plant.—C. E. A., *Otter St. Mary.*

"To-morrow (Saturday), February 4th . . . will Sell by Auction, at their Offices, a large consignment of Rose Trees and Herbaceous

EARLY SUMMER IN THE NORTH-WESTERN STATES SEEMS NOT UNLIKE IT IS AT HOME.

A COOL RETREAT AT THE BOTTOM OF THE LAWN. A VERY ENGLISH GLIMPSE IN PORTLAND, OREGON.

helpful to us than those published in the eastern states, as they have severe winters and their growing season is so very short. We have practically no rain from July 1 till September, and expect to water our gardens for those two months,

Plants, including:—Dwarf Roses: Edu Ward Herriot Salmon, Louis Walter Silvery Rose, Carolina, Red Head, Arnold Jansen, Echo, Rothati, Edward Herriot, Ulrich Runner, Magna Charta, etc. Climbing Roses: Worthy Perkins, etc. Standard Roses: Than Coildruschtic (White), Gruss and Tiphot (Red), Cariohna Testout, Louis Walter (Silver), Ella Poulsee (Deep Rose), Jessie, Weeping Dorothy Perkins, Weeping Extable, etc. Rhododendrons, Box Trees, Rockery Plants, and numerous other Trees and Plants. The

Auctioneers respectfully solicit attention to the above Unreserved Sale of Choice and Rare Plants. Sale at 2 p.m."

[The above looks to us like an announcement from the "Hong Kong Howler"! The first mentioned Rose among the standards is obviously what less well informed people call Frau Karl Druschki! Like "Worthy Perkins," choice and rare!—ED.]

EFFECT OF DROUGHT ON ANNUAL PLANTS AND WEEDS.

I EXPECT many readers of THE GARDEN will have noticed the remarkable behaviour of seedlings during the past year. I sowed my annual flower seeds in the ground at the proper time and transplanted out the seedlings brought on in boxes; they rushed up, flowered and died or dwindled during the drought. Last autumn all the self-sown seedlings that I hoped to have seen in the spring rose up in great quantities, thicker than I generally get. Some Sutton's Giant Candy-tuft and annual Chrysanthemums formed buds, but were cut down by the frost after Christmas. The Night-scented Stocks, *Matthiola bicornis*, are in thick array, and *Linmanthes Douglasii* is like verdant grass in spite of frost and snow. What is most astonishing to me, however, is to find several plants of *Ionopsidium* in flower. I came across them the other day while weeding a part of the rockery. I sowed some seeds three years ago; they never came up. I had them one year and was so charmed with them because they flowered on quite happily through deep snow and thick frost, but they did not self-sow, so I bought more seed and was very disappointed at the result, and here they are now flourishing. My other surprise is the great quantity of weeds that suddenly appeared. This garden was in a very neglected state when we came, the chief enemies being Sow Thistle, *Sonchus oleraceus*; Chickweed, *Stellaria media*; and Bindweed, *Convolvulus arvensis*—the last two still have "pride of place," though in a much less degree. During the glorious summer no weeds appeared and I thought how simple the autumn work would be. At the beginning of the autumn I noticed masses of tender seedlings appearing in the herbaceous border. I carefully left them undisturbed to see what they would turn out to be; I had not to wait long, for I soon recognised they were thick carpets of Shepherd's Purse, *Capsella Bursa-pastoris*; the seed has been lying dormant over five years, as it is not one of the weeds I have had severe struggles with, only an occasional one appearing here and there and soon pulled up. Red Dead Nettle, *Lamium purpureum*, also has sprung up in all parts of the garden. I have put a glass shade over some of the *Matthiola* seedlings, hoping to keep them alive till spring, but in this Fen garden, unless it is an exceptionally mild winter, such things do not live. It will be a great joy if they survive; not so long to wait for their flowering. I like to have at intervals down my border *Eschscholtzias* and *Matthiola* together; the former is lovely during the day, hiding the dead-like appearance of the latter, and it is a joy on a warm moonlight night to stroll up and down, inhaling the sweet scent that is wafted on the dewy air.—A CHADWICK THOMPSON.

THE LITTLE GARDENS AT RHEIMS.

SINCE writing last I have received for the "Little Gardens of Rheims": Miriam Marston, 25, 6d.; Anonymons (Tewkesbury), seeds. I should like the kind donors of money to know that I intend spending it at a poor and courageous florist's in Rheims. He has built a hut to serve for a shop and a dwelling-place instead of those which were destroyed by shot and shell during the four years of bombardment. He and his wife are recultivating their land,

which was, of course, totally neglected during the war, and are struggling to reconstruct their business. They are such brave, hard-working people and generous, too, for they have given me gifts for their poorer fellow citizens! So the money will serve twice over. I wonder if there is anyone among your readers who, for the sake of doing a good work, would come and help me distribute and divide the seed packets during the next two or three months or part of that time. If so, such an one would have to pay his or her own expenses and would, of course, be unpaid, but the work is interesting and is pro-Entente. One comes into personal contact with these people, and none of them are hostile to the British! On the contrary, they feel grateful and friendly towards them. I am single-handed and there is so much to be done in visiting and advising the owners of the *jardinetts* and in working the garden of the Foyer Féminin. I am so grateful to you Mr. Editor for your great help. You would be repaid if you would come to Rheims in the summer and see the little gardens of the barrack villages.—VICTORIA SLADE, Foyer Féminin, Rheims.

MY LITTLE FORMAL GARDEN.

WHEN my "little formal garden" was being planned last year (a *very* long way) "after Grave-tye," I asked for suggestions improving on my simple plan. A kind reader helped me by advising the 15ft. square centre grass plot should be sunk, and hoped to "hear further news of it later on." So I now venture to write of further grand alterations and improvements. Four arches are being set up over the four paths where they enter the grass plot, and there are now twelve little Lane's Prince Albert Apple bushes (most lovely of all Apple blossoms) and six Louise Bonne Pears, the most beautiful, perhaps, in blossom, fruit and autumn foliage of all Pears. These in combination with the May-flowering Tulips form the fairest picture of all the year—in May. The grass plot was not dug low enough to please me, so is now being carried down some 2ft. to "rock bottom" *literally*. (Let not Mr. Clarence Elliott read this!) It is to have a layer of good soil and be sown with fine Fescue-grass by the advice of Mr. McDonald of Harpenden. All sorts of choice small bulbs will be planted in this next autumn. Now comes the feature. In the centre of the grass plot (and consequently of the whole garden) a little pond is being hollowed out of the rock and lined with Portland cement. This pond measures 3ft. by 18ins., and is 6ins. deep (to serve as a bird bath). Concerning this pond I am undergoing showers of "chaff." Pears are freely expressed that I shall fall in and be drowned. Mrs. "Busybee" says she thinks of buying a

broody hen and a sitting of duck's eggs. Other suggestions are made that I mean to go paddling in it or fishing for minnows, but methinks Hortensia would anticipate me in this last. I do not think I have introduced Hortensia to my GARDEN friends. She is a "common or garden" English tabby kitten, but her mother was guaranteed to be a "super-mouser." Hortensia fortunately proves to have inherited this quality, for Chaffinch Cottage is built on tithe-land and the garden is overrun with (presumably) "poor church mice." —ANNE AMATEUR.

EXTRAORDINARY SECTION TO AN APPLE TREE TRUNK.

CURIOUS PATTERNING OF THE CORE IN AN OLD APPLE TREE.

photograph, although good, hardly does it justice, the leaf-like shape and outline of the "leaves" in the centre having, in fact, a much more natural appearance. Possibly some of your readers may be interested and can tell me why the design has taken this peculiar and interesting natural shape. —ARTHUR TROWER.

THE BUSH APPLE TREE.

I AM sure all interested in the pruning and training of Apple trees must feel indebted to Mr. Pearson and Mr. Thomas for the very practical manner in which they have expounded their different views in recent issues of THE GARDEN. Their different views on pruning may both be right as far as they go, but each talks of his own particular style of tree. Many people admire what Mr. Thomas calls the cordon-trained

GARDENING OF THE WEEK

FOR NORTHERN GARDENS.

The Kitchen Garden.

bush, but not all varieties are suitable for this system; many never get so rigid as he maintains they do. Stakes must be employed or some of the branches be tied to stronger ones in some cases if the trees are carrying a heavy crop. There is no doubt, however, that the system he so well advocates has been practised with success by the gardeners of other days, and I have long been of the opinion that these old gardeners knew more about the best methods of Apple culture than do most of those of the present generation. The point, however, which I wished to make was that the natural habit of the particular variety is the main thing to be studied. I do not think Mr. Thomas would try to grow a cordon-trained bush of, say, Ecklinville; this variety makes a beautiful pyramid, and as such it should be grown. Bramley's Seedling, Mère de Ménage and others of a straggling habit would not be suitable for cordon-trained bush trees. Some varieties, again, will not tolerate severe pruning—Gladstone, for example. It seems to me that no hard and fast rule can be laid down. I know that some growers would agree with what Mr. Pearson says: "I have long ago come to the conclusion that of all the evils which fruit-growers suffer from, close pruning is the most disastrous." I do not agree with him in every case. Certain varieties will stand close pruning, others will not; they cannot all be treated alike. Had Mr. Pearson given a list of those kinds which, grown as pyramids, gave the best results, and Mr. Thomas done the same with those which in his opinion did best as cordon-trained bush trees, I think their contributions would have been of even more value than they are.—P. McCOWAN.

A FLORA OF THE PYRENEES.

I NOTICED an enquiry a little while ago in your paper for a good book on the flora of the Pyrenees. It may be of interest to your correspondent to know that there is such a book published in France which, I believe, is still obtainable. It is "Flora du Département des Hautes-Pyrénées," par L'Abbé J. Dulac, published by F. Savy, Libraire Editeur, rue Hautefeuille, 24, Paris, 1867.—PETER R. BARR.

VEGETABLE MARROW ROTHERSIDE ORANGE.

I REMEMBER Mr. Herbert Chapman showing me some fruit of this variety at one of the R.H.S. Tuesday Shows before he had parted with the original stock. Unless my memory has played me false, it was an almost round fruit about the size of a croquet ball and in colour a buff-orange self. In war-time I bought Gourds because of their well known keeping properties, as in common with many another our garden standpoint was then pretty well reversed. "C. P." in the *Manchester Guardian* put the idea very well in true Kipling style:

"You must dispossess your head of the fallacy that bread is not man's only stay;
Know a plant that isn't eaten is unqualified to sweeten or beautify the day;
That a Lily or a Pansy's not so exquisite a fancy as Leeks and Cabbages;
That Solomon of story once in all his glory was arrayed like one of these."

Since 1918 Gourds have been given a miss and Rotherside Orange Vegetable Marrows substituted. Our experience has been that it is not fixed either in colour, shape or size, which is unfortunate, as the flavour of the true variety is so excellent. Shall I say, as Careless among Gooseberries, so is Rotherside Orange (green and orange striped especially) among Vegetable Marrows? To make a long story short, last year we had the same diversities along with a bumper crop.—J. J.

Peas.—Choose a well enriched portion of the early border for a first sowing of Peas in the open. Where the soil is cold and of a clayey nature a deeper seed drill should be made so allowing for a dressing of old potting soil or other light material, both before and after sowing. Treated thus, germination is more regular and growth more vigorous in every way. Soak the seed in paraffin for a short period before sowing, at the same time giving it a dusting over with red lead, as this proves an excellent deterrent to the ravages of birds or mice in the seed drills. The Pilot, Gradus and Sutton's Early Giant are dependable varieties, while American Wonder and Little Marvel are varieties that can be commended where dwarf growing sorts are desired.

Parsnips.—Where these have been left in the ground during the winter, the crop should now be lifted and stored in cool quarters. The ground may then be prepared for the reception of other crops.

Seakale.—It is also now advisable to lift the remainder of the crowns intended for forcing. Place these closely together at the foot of a north wall or pack in sand in the frame ground until required. Lay aside roots suitable for propagating and have them prepared during inclement weather. Tie the thongs into suitable sized bundles, placing them on end in boxes and cover over with 2ins. or 3ins. of soil until planting time arrives.

Leeks.—Where roots of these are desired early in the season sow some seed in a box indoors now and treat in a similar manner to that recommended for Onions on page 11.

The Hardy Fruit Garden.

Raspberries.—Tie in the necessary fruiting canes and cut away all superfluous or weakly growths. Stir the surface soil lightly with a fork and give a generous mulch of farmyard manure. Newly planted canes should be cut back to within 6ins. of the ground and in this way encourage the production of strong canes for next season's fruiting.

Fruit Under Glass.

Early Vineries.—In houses started some time ago growth will be active and disbudding will now require attention. Considerable care must also be accorded the Vines in regard to atmospheric conditions, as with lengthening days the sun becomes more powerful. Should the weather prove mild, a night temperature of 60° may be maintained, but should it be cold it may well drop 3° or 4° in preference to hard firing. Care should be taken not to over-charge the atmosphere with moisture should dull or foggy weather prevail.

The Flower Garden.

East Lothian Stocks.—Seed of these should be sown now and the resultant plants will be found to flower profusely during the autumn months. Sow in boxes of light porous soil and place in mild heat. Immediately the seedlings show through the soil place them in a light, airy position, so that dwarf and sturdy growth may be obtained. When large enough to handle prick out into frames or boxes and keep as near to the glass as possible.

Sweet Peas.—To save disappointments and in many cases failures, it is well to germinate the seed under glass and plant out during April. Sow now in pots or narrow boxes and start in a cool greenhouse or frame. Do not at any time allow the seedlings to become drawn or weakly. Water sparingly until the plants are well advanced and allow abundant ventilation during fine weather. The novice may well be embarrassed in making a selection from the many varieties now catalogued. If for ordinary purposes it is just as well to rely on the tried and tested varieties of former years, as it is impossible in many gardens to give the ever increasing list of novelties a trial. If in doubt state the colours desired and leave to the discretion of any reputable seedsman, who will readily help in this respect.

Jasminum nudiflorum.—Prune this delightful plant immediately its flowering season is over. Neglect in this respect readily causes accumulations of weak and unripened growth. In cutting out the older growth the new shoots are allowed proper development for flowering the following season.

Hybrid Foxgloves.—Where young stock of these plants has been raised with a view to transplanting in the shrubbery, the work should be carried through as soon as possible. When planting in the

wild garden or on the margin of ponds the groups should be formed in irregular fashion, guarding against anything pertaining to formal arrangement.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock, N.B.

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Potatoes in Frames.—Where it is convenient for a number of frames to be given up to early Potatoes a start should be made as soon as possible. Bottom-heat, such as produced by a bed of leaves and straw litter, will prove of immense advantage in enabling the plants to make a good start. Should a hot-water pipe run through the frames it will not be so necessary to provide the bed of leaves, etc. Let the soil have a liberal amount of nice flaky leaf-mould in its composition. For this early supply, the tubers need only be about 10ins. or 12ins. from each other and the rows about 15ins. or 18ins. apart. All sets should be nicely sprouted before being planted.

Sprouting Potatoes.—For early work out of doors this should be done at once if not already seen to, by placing the tubers on end in shallow trays or boxes and standing the latter on staging or shelves in a light, airy position safe from frost.

French Beans.—From now onwards this greatly prized early vegetable may be produced in a fairly satisfactory manner even though artificial heating is at a minimum, provided a good hot-bed of leaves and litter can be made up. When the bed is ready place 9ins. to 12ins. of good soil on it, and by the time the heat begins to decline have a batch of plants ready to put out; or seed may be sown in rows on the bed itself. Choose one of the recognised early varieties for this sowing.

Celery.—To provide an early supply a pinch of seed should be sown now in a box of light soil and placed in a warm pit. When the young plants are large enough to handle prick out into boxes or, better still, on a declining hot-bed.

The Flower Garden.

Shrubberies.—The necessary pruning and thinning out in these quarters having been finished, the ground should be dug over. Do not dig deeply and thus injure roots, but do so sufficiently to bury all the decaying leaves which have accumulated. The burying of these leaves is often of immense benefit to the roots of the plants, and it is quite a wrong practice to collect and remove them, unless there is a particularly sound reason for doing so.

Spiræas.—For the margins of water or for almost any damp part of the grounds or woodland drives these plants are admirable, and planting can be carried out for several weeks yet. There is a wide choice to make a selection from, and the flowering period is from spring until the autumn. A few worthy of note are S. Anthony Waterer, S. Aruncus, S. arifolia, S. canescens, S. cantoniensis, S. Douglasi, S. Filipendula and S. tomentosa. Should any pruning be necessary the early-flowering varieties could be done when flowering is over, and the later ones before growth recommences in early spring. To obtain the best effect Spiræas require to be boldly massed, and they rarely look happy mixed up with other shrubs.

Border Carnations.—Where these were potted up and wintered in cold frames the transferring of them to the borders can be carried out now, providing weather and soil conditions are suitable. Their lateness of flowering is a great drawback when early summer displays are required, so a groundwork of an earlier flowering plant, such as Violas, should be arranged for.

Antirrhinums sown in the autumn and growing in cold frames in a few inches of soil must be finally hardened ready for removal to their flowering positions as soon as possible. These plants will provide a fine early display, to be carried on by their January and February sown colleagues.

Fruit Under Glass.

Peaches and Nectarines.—When these trees begin to open their flowers a drier and more buoyant atmosphere should be maintained as an aid in obtaining a more satisfactory setting of fruit. Keep the hot-water pipes nicely warm, and whenever the weather is mild and genial, admit a goodly amount of air by the top and

bottom ventilators, but watch the latter very carefully when cold winds are blowing. At this early season of the year bees and other insects are not very free on the wing, so fertilisation should be assisted by lightly dressing the blooms with a camel-hair brush or rabbit's tail. This operation should be carried out towards midday and a further slight assistance may be given towards the obtaining of a good set by smartly tapping the trellis and the tree's main branches. Recommence the syringing of the trees as soon as a crop is assured, and watch carefully for any sign of green fly, which, if it does put in an appearance, should be at once checked by a light fumigation. Should there be any suspicion of dryness at the roots, whether growing in pots or borders, give a good watering with luke-warm water.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

CONSERVATORY AND GREENHOUSE.

Luculia gratissima.—This beautiful greenhouse shrub is not so generally cultivated as it deserves to be. Probably this is due to the fact that it is by no means easy to propagate. With its great trusses of deliciously scented, rose-coloured flowers, it is one of the choicest plants for a cool greenhouse. It is best planted in a bed or border, for it is one of those plants which is seldom happy for any length of time under pot cultivation. *Luculia gratissima* usually flowers during late autumn or winter, and after flowering it should be kept on the dry side at the roots until spring, when it should be pruned hard back, as it produces its flowers on the current year's growth. A native of the Himalayas, this plant is readily raised from seeds. The young plants usually take three years before they flower, seedling plants proving rather variable in quality. Thus good forms must be propagated by means of cuttings. This is best done by means of young growths some 3ins. or 4ins. in length, which should be put singly into small pots and placed in a propagating case with some bottom heat at command. It is most important not to allow the cuttings to flag, it even helps if the leaves are supported and kept in an upright position. I have rooted it successfully on several occasions by means of internodal cuttings, a method which I would advise all cultivators to try when they fail with the usual nodal cuttings. Internodal cuttings are cuttings taken between the nodes, not at a joint. Clematis may be given as an example, while all the Acanthaceae root very readily from such cuttings. One frequently finds it stated that *Luculia* is easily propagated by means of cuttings—a sure proof that that particular writer has never done so. *Luculia Pinceana* has white flowers, but this species is at present rare in cultivation.

The advice to plant out *Luculia* leads me to suggest that many conservatories under present circumstances might have at least a portion of their area planted out with interesting shrubs, as most of them do much better and are less trouble planted out than when grown in pots. Where it is proposed to follow this method of cultivation, existing beds or borders used for standing plants on should be cleared out to a depth of 2½ft. to 3ft., as ample drainage is always essential in such beds or borders indoors. If the soil is 2ft. in depth it is ample for most plants, and less may be used for some. The soil used should not be too heavy, but should have plenty of coarse sand or other gritty material mixed with it, and thus ensure free drainage, for in this connexion we must bear in mind that such borders indoors do not get aerated to the same extent as soil in the open air. Thus with frequent watering one must guard against the soil becoming sour. Sites for peat-loving plants can, of course, be specially prepared. All shrubby plants should be planted very firmly and if plants of any size are put out, the soil underneath them should be made very firm, in fact they are best planted on the top of hard draining material; if this is not done they are apt gradually to sink down until their stems become covered with several inches of soil, and this generally results in their death. There are no lack of suitable plants that may be used for this purpose. With the introduction of many beautiful single Camellias, this old-time favourite seems to be coming into favour again. *C. japonica* var. *grandiflora*, Lady Clare, *magnoliiflora*, Kimberley, a glowing red with a central boss of golden stamens, makes a beautiful table decoration if the flowers are floated in a shallow bowl. Among greenhouse Rhododendrons, done there is ample choice, the sweet-scented Edgeworthii hybrids being very popular, Lady Alice Fitzwilliam being one of the best of them;

also *R. Forsterianum*, *R. Veitchianum*, *R. ciliicalyx* and *R. formosum*, and many others. The beautiful Japanese hybrids are generally supposed to require a fairly high temperature, but I find they do perfectly well planted out in an ordinary conservatory, where the temperature in winter is often down to 45° during the night. Chorizemas, Pimeleas, *Daphne odora*, a many of the smaller growing Acacias, in fact all the smaller growing Australian and New Zealand shrubs may be expected to succeed when planted out. The few plants mentioned will serve to indicate the wide range of plants that may be used. The gardener will soon find plenty of plants to experiment with.

Cannas are very useful plants for furnishing the conservatory during the summer months; if grown in large pots and kept well fed they generally do good service until *Chrysanthemums* come along. If large specimens are required, 12in. pots should be used, putting several good rhizomes in each pot. They should receive very little water until they have made some roots and commenced to grow.

J. COURTS.

Royal Botanic Gardens, Kew.

Awards to Vegetables on Trial at Wisley, 1921

THE following awards have been made by the Council of the Royal Horticultural Society after trials at Wisley.

BROCCOLI.

Awards of Merit.—Early Angers, sent by Messrs. Nutting; Early Feltham, Messrs. Watkins and Simpson, and Barr; Spring White, Messrs. Sydenham; Snow White, Messrs. Sutton; Leamington, Messrs. Carter, Barr and Cooper Taber; Champion, Messrs. Barr, Nutting; April, Messrs. Finney; Evesham Giant, Messrs. Watkins and Simpson; Eastertide, Messrs. Sutton; Roading Giant, Messrs. Sutton; White Emperor, Messrs. Barr; Alexandra, Messrs. Scarlet; Edinburgh Market Late, Messrs. Scarlett; Eclipse (Cattell's), Messrs. Cooper Taber; Swan, Mr. Clucas; Late Queen re-selected, Messrs. Carter; White Mammoth, Messrs. Barr; Edmonton, Messrs. Watkins and Simpson; June, Messrs. Clucas, Finney, and Nutting.

Highly Commended.—Late Feltham, sent by Messrs. Watkins and Simpson, and Barr; Victory, Messrs. H. Hill; Model, Messrs. Dawkins; Tender and True, Messrs. Woodward; Satisfaction, Messrs. Sutton; Lathom Late, Messrs. Artingstall; Longstander, Messrs. Barr; May, Messrs. Nutting; Latest of All, Messrs. Sutton.

Commended.—Mid Feltham, sent by Messrs. Watkins and Simpson.

CAULIFLOWER.

Awards of Merit.—Feltham Forcing, sent by Messrs. Watkins and Simpson; Improved Large Erfurt, Messrs. Sutton; Early Dwarf Erfurt, Messrs. Nutting; Early Emperor re-selected, Messrs. Carter; Early Favourite, Messrs. Barr; Early Dwarf Midsummer, Messrs. Barr; St. Omer, Messrs. Davidson; Magnum Bonum, Messrs. Sutton; Purity, Messrs. Sutton; All the Year Round, Messrs. Simpson, and Sutton; Empress, Messrs. Dicks; Incomparable, Messrs. Barr; Autumn Giant, Messrs. Dobbie.

Highly Commended.—Forerunner, sent by Messrs. Carter; Early Dwarf Best of All, Messrs. Barr; Snow White, Messrs. Clucas; Enkhuizen Market, Messrs. Barr; Snowdon, Messrs. Dawkins, Clucas; Autumn Queen, Messrs. Barr; Summer Favourite, Messrs. Speed; Snowman, Messrs. Toogood; Walcheren, Messrs. Cooper Taber, and Dobbie; Late Giant, Messrs. Dawkins; Metropole, Messrs. Kelway.

Commended.—Eclipse, sent by Messrs. Barr, Nutting, Kelway; Johnson's Market, Messrs. Barr.

CELERY.

Awards of Merit.—Golden Self Blanching, sent by Messrs. J. B. Rice; White Plume, Messrs. Barr; Early Rose, Messrs. R. Veitch.

Highly Commended.—Paris Golden Yellow, sent by Messrs. Barr; Dwarf White, Mr. Clucas; Dawn, Messrs. Carter; Paris Rose, Messrs. Barr; Easy Blanching, Messrs. J. B. Rice; Defiance, (Bibby's), Messrs. R. Veitch, and Watkins and Simpson; Hawlmark White, Messrs. A. Dickson; Favourite Pink, Messrs. Dobbie; Perfection, Messrs. H. Miller; Matchless Pink, Messrs. A. Dickson; Giant Pink, Messrs. Carter; Champion Pink, Messrs. F. Dicks; Standard Bearer, Messrs. Carter, and Watkins and Simpson; Covent Garden Red, Messrs. R. Veitch, and Watkins and Simpson; Exhibition Pink, Messrs. Ryder.

Commended.—Champion Solid White, sent by Mr. A. Barr.

CELERIAC.

Highly Commended.—Ne Plus Ultra, sent by Messrs. R. Wiboltt; Giant Prague, Messrs. Watkins and Simpson; Giant Smooth Prague, Messrs. Barr; Large Erfurt, Messrs. R. Veitch; Celeriac, Messrs. Simpson.

TOMATOES.

Awards of Merit.—Aviator, sent by Messrs. Dickson and Robinson; Kondine Red, Messrs. Watkins and Simpson, Sydenham, and R. Veitch; New Sceptre, Messrs. Dawkins; Beattall, Messrs. Laxton; Hillside Comet, Messrs. R. Veitch; Golden Nugget, Messrs. Barr.

Highly Commended.—Victoria, Whole Salad, sent by Messrs. Burpee; Ailsa Craig, Messrs. Lowe and Shawyer, and Rochford; Orange Sunrise, Messrs. Watkins and Simpson; Golden Sunrise, Messrs. Barr.

Commended.—Water Baby, sent by M. A. Balch.

OBITUARY

MR. WILLIAM BAIN.

THE death, in his eightieth year, of Mr. William Bain severs another link with the past. He will be mourned by many with whom, at one time or another, he came in contact. Mr. Bain was for many years head-gardener to the late Sir Trevor and Lady Lawrence at Burford Lodge, Surrey.

The British Carnation Society's Spring Show, to be held in the Royal Horticultural Hall, Westminster, on March 21, judging from the comprehensive schedule and attractive prize list, promises to be of especial interest. Lady Mond is President of the Society, and the Committee, under the Chairmanship of Mr. J. S. Brunton, is showing considerable enterprise in its efforts to make the forthcoming show the best ever held under the Society's auspices. In addition to numerous increased money prizes for growers and gardeners, valuable challenge trophies are presented by Lord Howard de Walden, Mr. Reginald Cory, Mr. George Monro and others. There are special classes and tempting prizes for florists, notably Class 51, Decorative Exhibit of Carnations on table space 15ft. by 6ft. first prize Covent Garden Challenge Trophy, value £20 and £30 cash, second prize £30, third prize £20. These prizes should bring out London and provincial florists as competitors. The schedule, which is modelled on the Society's new colour classification of varieties, may be obtained post free from the Honorary Secretary, Mr. F. F. Bunyard, 57, Kidderminster Road, Croydon.

BATH'S BORDER CARNATIONS, &c

For Present Planting.

We make a great speciality of Carnations, and our stock is unequalled. The plants are very strong, perfectly hardy, and will satisfy the most fastidious buyer. The following Sets are selected from our unsurpassed collection of 450 varieties, and contain the cream of the new and older sorts.

- Set A.**
One dozen extra fine varieties for 15/-, Carriage Paid.
- Celestial.—A brilliant yellow self 2
 - Elaine.—A grand white; perfect petal and form 1
 - Hercules.—Crimson-maroon; perfect form 1
 - Innocence.—A lovely blush-pink 1
 - Romeo.—Yellow, suffused and marked pink 1
 - Isolde.—Raspberry-red, very distinct 1
 - Salmon Clove.—Salmon-pink; clove scented 2
 - Opalesce.—A lovely ros-madder 1
 - Lord Tennyson.—Yellow, distinctly edged rose 1
 - Duchess of Wellington.—Deep lavender 1
 - Red Emperor.—Rosy-red, extra large flower 1
 - Dignity.—Crushed-strawberry self, lovely 1

- Set B.**
One dozen choice varieties for 11/-, Carriage Paid.
- Bookham White.—Pure white, perfect form 1
 - Glamour.—Clear bright yellow 1
 - Vanity.—Brilliant madder red 1
 - Caprice.—Pink, mottled red; fine form 1
 - Contrast.—White ground, edged velvety crimson 1
 - Jean Douglas.—A scarlet self, dazzling colour 1
 - Queen Alexandra.—Buff-yellow, very free 1
 - Pink Beauty.—Rich clear pink, very vigorous 1
 - Miranda.—Salmon-pink and lavender grey 1
 - Climax.—Buff-yellow and coppery red 1
 - John Knox.—Dark crimson; perfect form 1
 - Lady Greenall.—Rosy-red shading to pink 1
- Bath's Popular Set of 12 Fine Named Varieties of Carnations and Picotees. Price 8/6, carriage paid.

BATH'S GOLD MEDAL DELPHINIUMS.

These plants are remarkably handsome in the border, and during the early summer and autumn the bold and stately masses of brilliant blue or purple produce a striking effect unequalled by any other flower.

- One dozen extra fine varieties for 21/-, Carriage Paid.
- La Tendresse.—Light blue and mauve 2
 - Lorenzo de Medicis.—Soft blue, shaded pink 2
 - Novelty.—Royal-blue, yellow and black centre 2
 - Rev. E. Lascelles.—Oxford blue with conspicuous white eye; magnificent 2
 - Willy O'Brien.—Purest ultra-marine blue 1
 - Rozenlust.—Mauve, edged Cambridge-blue 1
 - Reependens.—Pale blue, tinted mauve 2
 - Mrs. Caron.—Gentian-blue, white centre 1
 - King of Delphiniums.—Gentian-blue and plum, white eye 1
 - The Alake.—Intense dark blue with white eye 2
 - Pannonia.—Brilliant ultra-marine blue, white eye; distinct and beautiful. A.M.F. R.H.S. 1920 3
 - Musis Sacrum.—Bright sky-blue, early 2

BATH'S GOLD MEDAL PÆONIES.

The most gorgeous of all garden flowers. Requires less cultural attention than almost any other plant. Exceedingly hardy, its vigour and beauty increases year by year.

- Set A.**
Twelve glorious richly fragrant varieties for 25/-, Carriage Paid.
- Albert Crousse.—Pinkish blush; very large 3
 - Duchesse de Nemours.—Snow-white; very free 2
 - Mme. de Gathau.—Soft pink, enormous flowers 2
 - Marguerite Gerard.—Delicate flesh, sulphur centre, enormous 2
 - Lady Carrington.—Flesh; very large 3
 - Marie Lemoine.—Pure white; late; extra fine 2
 - Mme. Calot.—White, tipped rose; extra fine 2
 - Mme. de Vetry.—Pink, white centre 2
 - Mons. Chas. Leveque.—A lovely silvery blush 2
 - Festiva Maxima.—White, tipped blood-red 2
 - Solfaterra.—Beautiful primrose-yellow 2
 - La Tendresse.—Flesh, shading to white 3

R. H. BATH, LTD.,
The Floral Farms, WISBECH

ELSEWHERE in this issue will be found some account of the annual general meeting of the Royal Horticultural Society. The President, Lord Lambourne, while expressing his gratification at the flourishing condition of the Society, said that it must expect the ups and downs incidental to all undertakings. With an annual income from subscriptions alone of upwards of £23,000, and with a balance of more than £4,000 to the good after meeting all expenditure, it must be conceded that the Society is, financially at any rate, in a sound position. The R.H.S. withstood with unimpaired credit the trials and difficulties incidental to a great European war, and now that the tide of labour costs and general charges has passed the flood, it should presently ebb rapidly. It is not easy, then, to see what blows of adverse fortune Lord Lambourne can imagine as impending, unless the Society lose caste and popularity by mismanagement and shortsightedness. Lest such misfortune should befall, we would earnestly ask Lord Lambourne, who is justly and universally esteemed for the very arduous work he has done for the Society, seriously to consider the following points. It is, his Lordship will have well in mind, the on-looker who sees most of the proceedings, and though some of the following remarks are critical, they are not written for the sake of criticism.

R.H.S. Awards.—The Society has lately made a new and, we think, valuable departure in establishing an award of garden merit. Many people will no doubt consider that garden merit is precisely what the award of merit and, indeed, the first-class certificate should have honoured from the first, but that is by the way. The new award is a worthy departure, and the Council are to be congratulated upon establishing it. It would, *prima facie*, appear that awards made after trial at Wisley are in reality awards of garden merit. Are they officially to be considered so? The R.H.S. and the National Rose Society are holding a joint trial of Roses at Wisley next season. The soil of Wisley is not exactly Rose soil, but its light character will manifestly suit some varieties

better than others. Can such a trial be considered satisfactory? The same point has, of course, arisen with many other trials, notably with the recent trial of Tomatoes, for instance. After all, trials at Wisley seldom do more than indicate the best varieties of a particular race of plants for *light soils*; yet on the results of these trials—on these results alone—the Society bestows or withholds its awards.

Plant Breeding.—The Council might well at the same time consider whether they are doing all that might be done to further British horticulture. They have spent, and have still to spend, a very large sum of money on the compilation and publication of a new edition of Pritzel's Index, which is certainly of more botanical than horticultural interest. There are many gardening enthusiasts who do not hesitate to say that the money would be much better spent in systematic plant-breeding experiments carried out at Wisley. Much public-spirited work has been carried out on these lines by private enterprise, but, as a rule, experiments are not carried to their logical conclusion, either because of want of money or on account of shortage of space. This surely is one of the objects to which the Fellows' guineas might profitably be devoted?

A Close Preserve?—It is only right that the Council should know that there is considerable

and widespread dissatisfaction with the majority of the recent awards of the Victoria Medal of Honour. It is not disputed that all recent recipients of this distinction have rendered service, even valuable service, to horticulture, but it is more than open to question whether some of them are, in fact, as they certainly should be, those who, not already possessing the distinction, have done *most* for horticulture. Service to horticulture can be rendered in many ways. It may well be rendered by a journalist! The Council, it will be granted, has, for this reason, done well to honour Mr. John Fraser. It may be rendered by the painstaking scientist, as worthily represented on the list by Dr. William Bateson, or by the intrepid and equally painstaking collector, a class which seems, of late, to have been neglected by the Council. There are, of course, gardeners whose all-round excellence entitles them to distinction. Beyond all these, however, are the men who by skilful but laborious endeavour have given to our gardens whole races of plants. The late James Douglas held this honour, but why, it may well be asked, award the V.M.H. to men of whom, whatever their abilities, few gardeners have even heard; while of such as C. H. Herbert, who has given us a new conception of the Border Pink, the brothers Allwood, who have also done wonders for Pink and

Carnation, and the giants, whose names are household words, who have revolutionised the Bearded Irises, none possesses the coveted distinction? The reason is not, in fact, far to seek. There is a great and increasing tendency—an unintentional one, no doubt—for the Council to legislate not for the benefit of the great majority of the Fellows—not for the advantage of British horticulture as a whole—but for the relatively small clique who run the machine. Work for the R.H.S. should not be a necessary antecedent to the award of the V.M.H. The promotion of *horticulture*, not the *Royal Horticultural Society*, should surely be the "acid test." We know that it is written: "They also serve who only stand in waiting." Does the Council by any chance think it should read: "They only serve . . . ?"

DELIGHTFUL FOR THE SMALL SHRUBBERY ARE ALL FORMS OF THE FRAGRANT PHILADELPHUS LEMOINEI.

HAREWOOD HOUSE AND ITS GARDENS

THE terraced gardens at Harewood House—a future home of the Princess Mary—are among the very finest examples we have of the tendency, which showed itself after Queen Victoria came to the throne, towards a return to the formal style. The work may be compared to that which was carried out at Wilton, where "Capability" Brown, who laid out the original grounds at Harewood, had destroyed the old formal gardens dating from the first half of the seventeenth century. At Harewood there was no earlier formalism as the house was erected on a new site during the first years of George III's reign, when Lancelot Brown was reaching the height of his popularity, and it was not till 1843 that Sir Charles Barry reconstituted the south front of the house, heightening the wings to add bedroom accommodation, removing the central portico and making, from the house to the paved terrace, the magnificent descent of steps that, in one of the illustrations, is seen rising to the level of the main floor of the house which, owing to the rapid slope of the ground, is here raised up on a lofty undercroft. This illustration shows the extent of Sir Charles Barry's work, for it not only gives a glimpse of his altered house elevation, of the main stairway down from it, of the terrace and its lesser descent to the floral parterre, but also shows the grand balustraded and bastioned retaining wall which is the final architectural boundary. Below that is a narrow territory of straight-lined grass

slopes and flats that divides the nineteenth century formality from Brown's "landscape" treatment of the great area on to which the house looks down. That is well shown in the other illustration, taken from towards the eastern end of the south front of the house. Here, beyond terrace and parterre, the lake is seen lying in its hollow. A softly undulating section of the park, set with occasional trees, sweeps down to its eastern bank. A well timbered height shuts in its northern side and above rises the loftier and more distant ridge. Another woody hill shuts out the western end of the lake and the extensive plantations screen the kitchen gardens—far removed from the house, in true Brownian manner—when grassy slopes and winding ways, often represented by artificial mounds and meaningless serpentine—were brought right up to the four walls of the house. Much of Brown's lake-making and tree-planting, however, was good, especially after time had taken a hand in remedying the artificiality of the curves of the timber clumps and water edges. That, in very high degree, has happened at Harewood, where the newer terraces amply satisfy the feeling for architectural and geometric outthrusts to the great classic house, and where nature has so far resumed her sway over the far stretching grounds as to give a sense of tempered wildness and free beauty.

Very different was the scene in 1753, when Edwin Lascelles, succeeding his father in the great Harewood and Gawthorpe estate, felt that Gawthorpe

Hall—the old home of Gascoignes and Wentworths that had only become Lascelles property in 1739—was, in size, style and position, below the mark for a wealthy man of George II's time. The old house stood by the water, which had not yet assumed a lakelike character. An engraving of 1722 shows an ample house of ancient origin, with post-Restoration alterations and additions, including the walled and formal gardens of that period. Northwards from it the land rose to the point where the ruins of Harewood Castle still stand, and some three or four hundred yards up this slope was fixed upon for the sumptuous mansion which was to encompass all that John Carr and Robert Adam could contrive that was best and newest of its day. Begun in 1759 the house was not complete until 1771, when the family moved into it and the old hall was demolished, all trace of dwelling and walled gardens being obliterated as wholly irreconcilable with the landscape effects which Brown was to carry out in its immediate environment. There the stream became a lake covering fifty acres and the adjacent slopes became "belts" and "clumps" of Beech and other trees. In more recent times there has been in this region a further development of garden amenity. The surface of the lake is dotted with Water Lilies, and from its banks rise such moisture-loving subjects as reeds and Astilbes, Irises and Water Forget-me-nots. A long walk through the Beech woods brings you to the kitchen garden, not wholly given up to the edible Cruciferae

HAREWOOD HOUSE. A GENERAL VIEW OF THE TERRACES.

and Papilionaceæ, but also to their floral cousins, such as double Rockets and Lupins, that flourish amid many other old-fashioned flowers in ample borders. Nor must we forget the glass houses,

against the sombre green of the noble summer-clad trees that form the background. In the parterre the growth and colour-riot of the bedding plants are checked by the note of severity given by the

Yorkshire is a beautiful county. In dale and dell it is often scenic and grand. In softer moods it is rich and smiling. Harewood is on the edge of such contrasting regions. From the higher points of the park the eye can roam on one side up Wharfedale and on to its enfolding moors, while on the other side the vale of York stretches out its fertile expanse, and on clear days the twenty mile distant Minster towers are seen rising at the horizon. But landscape and horticultural amenities by no means exhaust the catalogue of Harewood's charms. The interior still shows much of the decoration and furniture which, as surviving drawings prove, Robert Adam designed for it in 1765 and following years. The ceilings of saloon and gallery are the most striking of the many he introduced. The music room has not only the ceiling he set there, but the carpet which he had wrought in corresponding design. All the wall incident, doorways and chimney-piece, stucco panel and framed landscape, remain untouched and combine to make the room historically the most perfect as well as artistically one of the most beautiful in this house of splendid interiors, furnished not only with the admirable pieces that Chippendale produced for the first Lord Harewood from

A PORTION OF THE PLANNED GARDEN.

where a vinery has long been the home of a Muscat of Alexandria that rivals in size and age the Hampton Court Black Hamburg. A tablet informs us that it was planted in 1783 and that the house that contains it was enlarged for its accommodation in 1839. The woodlands afford scenes of great beauty. Beech and Birch, Cherry and Robinia rise high and leave gaps for the sheltered and half-shady homes of massed Rhododendrons. Oaks also flourish, and near the house are ancient Cedars of Lebanon—so frequently a legacy from Lancelot Brown, who used them freely and well.

Good design, full purse and splendid local free-stone quarries combined to give ample dignity and rich extent alike to eighteenth century house and nineteenth century terraces. The house is 250ft. in length, the formal gardens extend 100ft. beyond it at each end and 150ft. before it to the south, so that this grand group of highly wrought architectural incidents occupies an area of two and a half acres. Size alone may merely yield a sense of clumsiness and oppression. Not so here. Sir Charles Barry contrived to maintain a unity of design in the house he altered and the gardens he added. Forms, proportions, details are individually right and are harmoniously blended into a disciplined whole, where house and stairway, terrace and retaining wall, parterre and fountain, statuary and vase, take their place in regimental subordination and uniformed array. It is big and splendid, but also it is harmonious and sympathetic. Glancing again at the illustrations, how arresting is the long line of balustrade, with its ordered breaks of bastion and steps broadly framed by the continuous and restful extent of grass bank below and gravel walk above. The rich play of light and shade on the stonework tells delightfully

hue and form of the clipped Yews. The insistent note of architecture, so loud and strong in stately step and balustraded wall, is sufficiently struck in the floral area by the great stone-backed benches at either end and the intervening many-angled pools from which rise statuary fountains.

Harewood is just sufficiently separated from Leeds by distance and intercepting hill to retain its rural aspect. Where mines and manufacture have not seared its surface and thickened its atmosphere,

Adam's designs, but also the spoils of France—gilt Louis XVI suites, Beauvais tapestries and Sèvres china—which the second Lord obtained as wreckage saved from the storm and stress of the French Revolution. At Harewood for a century and more they have lain in safety and in peace. May that be likewise their future destiny, as also of their present proprietor, the fifth Earl of Harewood, and after him of his son and Royal daughter-in-law.

H. AVRAY TIPPING.

THE GREENHOUSE PRIMULAS

PRACTICAL NOTES ON THEIR CULTIVATION IN SCOTLAND.

Southern readers should find the following notes helpful if they bear in mind that it is unwise here to sow until, at any rate, the middle of April.

WITH the lengthening days the Primula is making a great show in the conservatory. One wonders what the conservatory could have been like at this season of the year before the Primula made its appearance in all its varieties and gay colours.

First we have the Star varieties in all their glorious colours, with beautiful stellata flowers tiering above the elegant cut foliage. What glorious effects may be produced if the colours are well chosen for grouping. White Star and Pink Star used together make a very fine group. Dark Blue Star and White Star grouped together and associated with a few plants of Primula malacoides also give a pleasing combination.

One very effective group is Dark Blue Star and Primula kewensis, the Dark Blue Star showing up the pale yellow flowers of kewensis. Primula kewensis gives little or no effect by itself owing, I think, to the paleness of its foliage, but if grouped with the Dark Blue Star or even with Primula malacoides it provides a combination that never fails to please.

Then we have Primula obconica with all its shades of mauve, approaching to blue on the one hand and to crimson on the other. This Primula seems happy anywhere and gives very harmonious and restful effects when grouped with other plants. The mauve flowers never seem to clash, as the colours of other Primulas are apt to do. One very happy association

is that of *Primula obconica* with *Arum Lilies*. The dark green foliage of the "Lilies" shows off to great advantage the pale mauve flowers of the *Primula*.

One of the most important points in the cultivation of these *Primulas* for keeping the conservatory gay during the winter and spring months is to make successional sowings from the end of February to the end of June. The last sowing provides plants for small pots suitable for the decoration of the dinner table. The best varieties for this purpose are *Primula malacoides* and the Star forms of *Primula sinensis*. The seed should be sown thinly and evenly. *Primula* seed, as a rule, germinates very irregularly. The soil for the seed-pans should be of a very light nature, with a good sprinkling of silver sand. Pass the whole through a quarter-inch sieve, the rough material that is left over being used for covering the drainage. Fill the seed-pan with the fine soil and make it firm, give a good soaking with a fine rose and allow it to stand until thoroughly drained before sowing. The seed sown, cover lightly with silver sand, as this tends to prevent "damping off" when the tiny seedlings come through. Place the seed-pans in a house with a night temperature of, say, 55°.

As soon as the seedlings begin to grow and show the first rough leaf, prick them out into boxes about 2 ins. apart and keep close for a day or two until they get well established in the new soil.

The soil for the boxes should be of the same nature as that used for the seed-pans, with the addition of a little powdered charcoal. In about ten days or so remove the boxes to a warm frame and keep them near the glass in order that the plants may be robust and stocky. Admit air without undue draughts. In due course they will require a shift into small pots; 3 in. is a very suitable size. The soil used for this potting should be a little rougher, with the addition of burnt ashes and soot.

The soil should be well firmed round the neck of the plants to keep them from rocking about. This applies to the Star varieties. Place them back in the frame and keep close for a few days, with light sprayings overhead until they recover from the check. After that air should be given on all suitable occasions to keep them growing stocky and prevent damping.

The compost for the final potting should consist of a nice, rich fibrous loam pulled to pieces with the hands, with the addition of good, flaky leaf-soil, burnt ashes, bone-meal, powdered charcoal, silver sand, and a 6 in. pot of soot to every barrow-load of soil.

After the final potting place the plants in a cool frame with an ash bottom. Frames facing north are to be preferred, as no shading is then required and they receive welcome cool-shaded light, so beneficial to the development of that nice dark green foliage. During the afternoons of bright days a light spraying overhead is very encouraging to their growth, especially if clear soot-water is used, as it keeps away all insect pests while growth is finishing. The frame-lights should be pulled off altogether at night, as the plants enjoy the heavy dews of late summer nights. When they commence to send up their flowers a house with a night temperature of, say, 50° to 55°, with plenty of air night and day, suits them well.

These past two seasons I have planted out *Primula malacoides* in the rock garden, and they have come through very successfully, withstanding 15° to 18° of frost, and to-day, after the heavy snowfall we have had, are pushing up their fairy-like *liac* flowers.

Forfarshire.

G. S. LONDON.

LITTLE GROWN BULBOUS PLANTS

The good points, failings and cultural requirements of the Tigridias.

FOR ordinary garden purposes *Tigridias* may be taken to be *Tigridia Pavonia* and its seminal varieties. These are half hardy bulbs whose ancestral home is Mexico. Whether all the varieties which we now have come to us ready made, or whether they are the result of a change of environment and have appeared for the first time in different parts of Europe I am unable to say,

a black and white print. We all of us, naturally, compare the new and little known to something we know very well; hence as I have used tea-dust to make my tea for many years, I invariably think of the necessary strainer that goes on the tops of the cups to keep the small bits out of the liquor whenever I see a *Tigridia* in bloom. The spotted centre is the perforated part of the strainer, and the three ears are the parts which fit on the top of the cup. With respect to colour, few flowers have more brilliant shades than some of these. Bright carmines and orange-reds, beautiful yellows and pure whites are all to be found in the different varieties.

Why, then, is the Tiger Flower so little known? The reasons probably are two: (1) The individual flowers only last a few hours, and (2) as they usually open in the night, long before evening comes they have turned into miserable-looking objects of incipient decay. I would urge, however, that the glory of a fair-sized bed on a sunny July or bright August evening, far outweighs all that can be urged against them.

They are just as easy to manage as *Gladioli* and require very much the same treatment. Plant in May, or earlier, in districts where there is no likelihood of frosts coming to injure the young foliage, in light, rich soil, 3 ins. or 4 ins. deep and about 6 ins. apart. Later on, when hot weather comes, give them a good mulching of old cow manure, or anything that will keep the ground moist. Occasional waterings of liquid manure when the plants are in bud and during the time of their blooming are immense helps and promote larger individual flowers and a longer period of bloom. My bed suffered greatly in the long period of drought last summer as there was no water to be had for

the garden; but, thanks I suppose to a plant here and there getting its feet into something it liked, we had a few fine specimens. One of these is figured in the illustration and was nearly 2 ft. high.

After the first autumn frost the bulbs should be lifted and the foliage completely dried, when it should be carefully broken off. The bulbs may then be stored in dry sand or light earth in a frost-proof place where no moisture can come, until the next planting time, when the larger ones may all be expected to bloom.

In preference to buying "mixed *Tigridias*," I would rather buy the bulbs in named varieties

A CHARACTERISTIC PLANT OF *TIGRIDIA PAVONIA*. THE VARIETY IS RUBY QUEEN.

Note the unexpected tiger's head in the flower as photographed.

Although the Kew Hand List (1915) is silent upon the subject of *Pavonia* hybrids, and so leaves us entirely in the dark as to their origin, one at any rate—*conchilora*—was introduced direct from its South American home in 1824, and *Pavonia* itself in 1796.

The illustration gives those who do not know *Tigridias* a better idea of the habit of the plants and the very uncommon shape of the flowers than any mere verbal description. The palm-like look of the leaves, the spotted central depression and the peculiar eared look of the flower as a whole stands out as its most obvious characteristics in

and make my own mixture. One can then control one's bed and only have the colours or shades one likes. For example, lovely as are the pure white grounds with their smart ruby-red markings, the contrast between them (*grandiflora alba*) and the red and yellow shades of *carminea*, *Ruby Queen*, *Pavonia speciosa*, *conchiflora* and others seems to me to be a little too violent to be altogether pleasing. On the other hand, there will be some who will think the introduction of a few whites makes a good foil to the brighter colouring of the others. *Chacun à son goût* is a very wise proverb to bear in mind when writing of matters of taste. Another thing that urges me not to commit myself is the difficulty of nomenclature. When catalogues do agree their unanimity is wonderful. Perhaps, however, I may venture to say that in my own "foolish

opinion" (a grand and never-to-be-forgotten phrase this of an old gardener I once had) *Pavonia speciosa* (orange-red), *lilacea* (syn. *Ruby Queen*) (ruby-red) and *conchiflora* (rich yellow) are among the most effective varieties. *Rubra*, *carminea*, *rosea*, *purpurea*, *Wheeleri*, *Le Géant*, *Le Géant Rose*, *alba*, *alba immaculata*, *canariensis*, *lutea immaculata*, *cœlestis* (?), *alba grandiflora* and *rubra grandiflora* are all to be met with in different lists. I do not know all of them, but of those I do, I can truthfully say some seem very much alike.

As *Tigridias* are not expensive bulbs, and may be had for about 3s. a dozen or less, might I suggest the getting together a little collection and the growing them in trial beds as a mild floral excitement for 1922. I feel sure a good many visitors will not know them. JOSEPH JACOB.

TOPIARY AS AN AID TO ADVERTISING

IT seems strange, at first sight, that horticulture, the earliest art practised by man, should, in these latter days, be brought into the service of the latest, viz., the art of advertising. Yet this is being advocated by a firm of publicity agents, who are using topiary work as a medium for advertisements. The idea is to utilise Yew trees, trained and trimmed into the semblance of birds, animals and objects of common life, as living announcements of somebody's foods, beverages, soaps, fountain pens or other commodities popularised by our "national" advertisers. Thus, for brands of tinned milk, butter or cheese, they are offered the figure of a cow, cut out of and in a growing tree; for eggs, whether fresh, "farmer's" or desiccated, they have Yew trees shaped like a sitting hen, or a duck; while for a popular make of margarine the agency suggests a tree clipped to resemble a pheasant! Yews can be easily trained and cut to form a circular, wreath-like growth, representing a lifebuoy; this would act well as an advertisement for a certain soap-making firm who use that nautical form of life-saver as its "strange device."

Swans, again, are common in topiary work, and trees so shaped obviously lend themselves to the advertising of a well known fountain pen. The manufacturers of dogs' biscuits, even, are catered for by means of a group of Yews bent and trimmed to represent a dog-kennel, with a small tree in front, cut like a dog! For a feather manufacturer there are trees shaped like an

ostrich, while cabinet-makers can have one so like an armchair that one feels tempted to sit in it. Brewers, wine merchants and distillers are easily accommodated, since bottle shapes are a common form of topiary work. Even shops, stores, theatres, cinemas, cafés and tea-rooms are similarly catered for. Teapots, cups and saucers, plates and loaves are easy to form in the yielding Yew, and trees so shaped would well serve to call attention to the establishments displaying them. Globular forms and ball-like growths are among the simplest to grow and trim; their uses, as advertisements, are many. Such articles as atlases, billiard balls, toy ballcons and ball-bearings are obviously subjects for advertisement by means of Yews so shaped, while a certain metal polish, using a globe as its cognisance, is simply "asking for" a globe-shaped Yew! But, so many are the forms which can be outlined by the plastic, patient Yew that the promoters of this novel publicity scheme profess themselves capable of catering for practically almost any demand by one or other of their vegetable advertisements—their, literally, growing announcements.

The main idea is to plant these shaped Yew trees alongside railway huses and main roads, replacing those hideous hoardings known as "field signs." Further, to identify the plant with the object of publicity sought by their display, painted aluminium lettering will be supplied to form the name of the firm, brand or proprietary article advertised. This will be suspended from and on the trees, while in the case of retailers, cinemas, cafés, etc., the shrubs may be planted in tubs, the sides of which will afford space for bold advertisement. The originators of this novel advertisement "stunt" estimate the cost of upkeep of these trees, including a yearly trimming, at £1 per annum, and they put the price of them at from 20 to 25 guineas each.

As growing and clipping a given design out of and in a Yew tree takes from eight to sixteen years, it is obvious that no advertiser, wishing to get rich quickly, could afford to wait for his special designs to be grown. Accordingly

the agency has purchased a large stock of ready shaped trees, and these it offers to artistically minded advertisers, only one "line" to be used by one maker of a given commodity. Lovers of Nature and horticulture will doubtless welcome this new system of vegetable advertisement and plant publicity, for these living pictures, these growing

SHE NEEDS BUT A PEN HUNG FROM HER BILL TO COMPLETE THE ADVERTISEMENT.

announcements, are certainly preferable to the blazing posters, the tin dogs, wooden watches and metallic cows at present desecrating the fields adjacent to our railway lines; they are, at least, natural in essence, if artificial in form.

E. W. RICHARDSON.

Lachenalias that are Sweet-Scented

FOUR out of every five people when they come to see my *Lachenalia*s say, "Now if you could get that scent (the scent of *glauca*) into those (the mixed-up hybrids of *tricolor*, *quadricolor* and *aurea*), you would find everyone would want them (the hybrids). It would make all the difference." I feel they are right, and for years I have been trying if one could not bring off a marriage between *glauca* and some of my best hybrids, but all to no purpose. There is an incompatibility of something which prevents them falling in with my plans, and at the end of their flowering season we are as we were. Next year there will be a sufficient quantity of *pallida* to allow us to try that variety, as by singular good luck we have a very late yellow variety with which to mate it. We live in hopes. Meanwhile may I put in a good word for both *Lachenalia glauca* and *L. pallida*. It may be partly from sentiment, as their delightful perfume brings to mind far distant days when the golden *Cytisus* was to be found in spring time in every well appointed conservatory, but they do appeal to me. The taller and larger bluey green *glauca* and the shorter and smaller *heliotrope* tipped *pallida* are both of them sweets of the sweet, and are well worth growing wherever sweet flowers are appreciated. They come into bloom when the last of the hybrids mentioned above are getting over, but except for the difficulty of experimenting in hybridisation, since all *Lachenalias* dislike anything approaching to forcing, this late blooming is no detriment. Of the two species *pallida* is the most reliable, and makes a more even potent than *glauca*, which is always a little erratic in its growth.

J. J.

WHO SAID PUPPY BISCUITS?

THOUGHTS ON THE TREATMENT OF INFORMAL STEPS

SOME few months ago (*THE GARDEN*, July 30, 1921, page 378) there was published an article which dealt at some length with the very important matter of garden stairways, but very little was said about the unpretentious, but very necessary, informal stairways which, properly treated, add greatly to the attractions of the wild or rock garden or other portions of the grounds which may be informally treated.

Very formal steps, even steps as formal as those illustrated on page 483 in the issue of *THE GARDEN* for September 24 last, detract considerably from the charm of an otherwise natural-looking rock garden. Not that steps need necessarily look as if they formed part of the geological formation upon which the garden may be supposed to rest, though it does, in such case, improve the appearance of the whole if some of the steps give that impression. The eye then feels that the others have been used to best advantage to join up Nature's handiwork. Needless to say, if such effects are to be attempted the design and execution of the whole garden must be of the best, or the illusion will fail and the whole thing look theatrical. We are wandering, however, and that is just what our steps should do; nor will it seem suitable to most of us to employ stone dressed to any extent even with the hammer, though obviously sharp corners which might damage feet or ankles should be removed.

On the steps, as in other parts of the rock garden, there is too often either a total dearth of furnishing, which is displeasing, or the planting is too obviously planting, too diversified in character and too spotty in effect.

Observe the quiet restfulness of the picture of the Woolly-leaved Thyme (*Thymus Serpyllum lanuginosus*) on an informal flight of stairs. This is, it must be allowed, one of the most effective of carpeting plants, but the sum total of effect is due not so much to the qualities of the plants themselves—lost as they partly are in black and white—as to the breadth of treatment. Quiet simplicity and dignity can only be obtained by breadth of treatment.

The other picture shows steps rather more substantial in character, adorned with a little

colony of *Campanula garganica hirsuta*. For a fairly important path, such as this obviously is, the planting seems just a thought too heavy. One feels that, after a shower of rain, walking up these steps would not be altogether a happy business for the feet and ankles! Had this been a bypath used only for attending or inspecting some of the gardener's treasures, this objection, needless to say, would not apply.

The treatment of steps and paths through the rock garden (leaving aside turfed paths or ways) is the most unfortunate part of many otherwise fine conceptions. To see admirably balanced masses of stonework, with the actual stones happily placed and the plants fittingly arranged, spoiled by an unnatural path of crazy paving, broken here and there by equally "crazy" steps, is a pitiable sight, but one far too common. It would be far, far better to gravel the path than to lay it so, for the crazy paving as generally laid forms a wretched kind of compromise between the natural and the artificial. A pathway formed of the same kind of stone of which the rockery itself is composed, and so laid in little shelving steps as to give the impression that the path has been formed by splitting it from its bed, is in a

A "CASCADE" OF *THYMUS SERPYLLUM LANUGINOSUS*.

totally different category. It represents an ideal worthy of attainment, and in many stones—and these the most suitable for rockery construction—easy to attain.

For situations where kindly Nature has provided no stonework, and Man has not thought fit to introduce any, rough steps formed of the natural earth (faced with gravel if the soil is of a sticky texture) and retained by balks of wood are useful. The rougher the timber used the better, as a rule, the effect. If a handrail is called for, it may be supplied. It will not be beautiful, but let it, at any rate, be secure and *look* secure. "Rustic work," so called, however employed, is an abomination; a worshipping of false gods. It has been said that, in the informal garden, steps may well be allowed to wander. Let us hasten then to say that by "wandering" something different is meant than a meaningless meander. One should feel, instinctively, that the course of the steps is induced by the lay of the land and by no other consideration.

There are few things in a garden which add more to its charm than happily placed and simply laid out stairways. Looking at the other side of the picture, there are few more unfortunate objects than an over-elaborate or ill-placed flight. Whether the flight be formal or informal, there seems to be but too much temptation to make it unduly complex and over-ornate. In the garden breadth of treatment and, above all, simplicity are essential.

SIMPLE BEAUTY. *CAMPANULA GARGANICA HIRSUTA* HAPPILY PLACED.

NEW AND RARE PLANTS

THERE was quite a good and interesting show at the mid-February meeting of the R.H.S. and a correspondingly good attendance, augmented, no doubt, by its being the occasion of the annual general meeting of the Society.

Primula Princess Mary.—The dainty little *Primula malacoides* is generally well known and appreciated for its graceful whorls of flowers. The species has, of late, been greatly improved upon, and of the several varieties *Princess Mary* is distinctly one of the best. The flower stems are much taller, and the more numerous whorls have larger and more substantial flowers of rosy mauve colour, but this greater size has not been obtained at the expense of grace and elegance. This variety seems to have a better constitution than most, for it is said that the plants do not damp off, as do so many others. Award of merit to Messrs. Carter and Co.

Miltonia Lord Lambourne.—That this new Orchid should receive both a first-class certificate and a silver-gilt flora medal indicates that it is

an exceptionally fine variety, and this is so. It is the most gorgeously coloured *Miltonia* that has yet been raised. The segments are deeply flushed with rosy carmine and have narrow white margins. Awards to Messrs. Charlesworth and Co.

Odontioda Cora.—The well formed blooms of this *Odontioda* are of greater size than usual, and they are well disposed on the erect spike. The colour is a warm chocolate maroon. Award of merit to Messrs. Charlesworth and Co.

Clematis F 559.—This is one of the new Clematises collected on the Da-Tung Alps in China and, awaiting investigation, was shown under the collector's index number. The plant had been forced into bloom, so it may not be a true indication of the merits of the novelty, which, judging from the specimen, is not great from a gardener's point of view, though it may probably appeal to the hybridiser. The plant is of somewhat straggly growth, the leaves were few and undeveloped, while the smallish flowers, which are borne on rather long wiry stalks were stippled

with pale blue. The blooms were set almost at right angles to their stalks and presented a semi-double appearance. Shown by Mr. A. C. Woodward, Arley Castle, Bowdley.

Saxifraga × Mariæ-Theresæ.—The plant on view was a little turf of glistening silvery leaves with short stemmed, bright crimson flower buds which expand to a very pale, almost washy, pink. The flowers are very small. Shown by Mr. P. Rosenheim, East Molesey.

Narcissus St. Valentine.—Several pots of this were shown, but they did not impress one as being of exceptional merit. It is a "Cyclamens of *Barrii* form". The chief attraction is the bright corona. Shown by Messrs. Herbert Chapman, Limited.

Although the Narcissus Committee met for the first time this year, and the florists' shops and many street hawkers are offering Daffodils in quantity, these flowers were singularly few in the hall. The most noteworthy representatives were the many blooms of grand *Soleil d'Or* at the back of a little group by Messrs. Barr and Sons. These Narcissi were of rich golden colour and served perhaps as a foretaste of what we may expect in the near future. There were a few

THE NEW "NAVEL ORANGE"—CITRUS SEEDLESS WASHINGTON NAVEL.

PRIMULA MALACOIDES PRINCESS MARY. THE PLANT IS GROWING IN A FIVE-INCH POT.

Crocuses, and the quaint Grape Hyacinths were to be seen in an occasional exhibit.

The greatest exhibit of spring bulbs was by Messrs. Segers Brothers, Dutch growers who do a strictly wholesale trade. They had many Tulips, including the Darwin Le Nôtre, of lilac pink colour, which, when forced, retains stiff stalks and does not flop over. Victoire d'Oliviette is darker than the carmine Bartigon and may be forced into bloom three weeks earlier. The double Tulip Mr. Van der Hoef is a good yellow, while El Toreador may be termed a crimson and fawn Keizerskroon.

The early Irises were again prominent among the alpine. *I. reticulata*, *I. histrioides* and its varieties were all beautifully blue, but the most uncommon and attractive was *I. persica*, a quite dwarf, sturdy Xiphion Iris, which is slightly violet-scented. The deep velvety blue blotches on the lip contrasted finely with the golden colour on the beardless keel. It was shown by Messrs. Waterer, Sons and Crisp, who, by the way, had quite the gayest and brightest of the spring flower exhibits. *Adonis amurensis* fl.-pl. drew attention to its quaintness in having a centre of vivid green inside a ring of golden petals.

The all too few plants of the charming little hardy Cyclamen were to be discovered in Messrs. Barr's exhibit. These were two varieties—*rosea* and *rubrum*—of the Caucasian *Cyclamen ibiricum*. The tiny flowers retain all the grace of the perfect *Cyclamen* form and were very brightly coloured.

The greenhouse *Cyclamen* was represented by gathered flowers of the Sheepwell strain from the gardens of Mr. E. Wormall, Sheepwell House, Potters Bar. These are said to be fragrant, but fragrance in *Cyclamen persicum* is an elusive quantity under the best of conditions, and we could not detect any, though perhaps the weather was too cold. The flowers, however, were well grown.

The great decorative value of their new *Primula Princess Mary* was well shown by Messrs. Carter and Co. in a large exhibit in which it figured abundantly, together with the *stellata* variety *Fairy Queen Improved*, interspersed with pots of miniature Hyacinths of many colours and bowls of Tulips.

Among greenhouse plants we noted *Begonia manicata*, which is now rarely seen in private gardens. It is an evergreen species of very easy cultivation in a cool greenhouse, and even when not in flower the large, stout, pale green leaves are handsome. The blush pink flowers are produced in long, branching cymes. It is an adaptable plant, equally as ornamental in a 5in. pot as in the largest size.

The most showy of the trees and shrubs were the sprays of *Parottia persica*, thickly studded with fat buds just bursting and disclosing the brilliant crimson filaments. A few warmer days would suffice to make the trees strikingly beautiful. In addition to its spring effect, this small tree is one of the best for autumn colour. Messrs. J. Cheal and Son showed it, and near by had a compact bush of the long-flowering *Pieris* (better known in gardens as *Andromeda floribunda*). *Sarcococca ruseifolia* is rather a rarity at the R.H.S. shows, but we noted a little colony bearing quantities of yellowish white flowers and the shining purple fruits of last year. It is not a showy shrub, but one that is useful for planting in shady places.

NEW FRUIT.

Citrus Seedless Washington Navel.—The large bright golden fruits attracted a deal of attention, not unmixed with a desire for acquisition, for they presented a most attractive appearance. Of their flavour one cannot speak, but if like the

common Navel Orange it should be good. The fruits were large, of flattish egg shape and possessed the characteristic navel-like centre. Award of merit to Messrs. T. Rivers and Son.

Besides the basket of fruits which received the award, Messrs. Rivers had, among a valuable collection of Citruses, heavily fruited bushes of this variety, the Horned Orange, Egg Orange (St. Michael's) and Thomson's Improved Navel Orange of the broad-leaved section. The Myrtle-leaved Orange was represented by a couple of small bushes, also heavily laden with golden fruits. This, which once was fairly common in the larger gardens which possessed the indispensable "Orangery," has now become rare in cultivation, but it is an ornamental bush for the cool greenhouse. Its habit is neat, the leaves are only a couple of inches or so long, of shining green colour, and the variety flowers freely under good cultivation. Another desirable Orange for the cool greenhouse is the Oonshiri or Satsuma Orange, shown as the "New Japanese Orange from California." The association is not clear, but probably the place of distribution is indicated. That, however, is as may be, but it fruits freely as a medium-sized bush, and the dark green leaves are of moderate size. The fruits are similar in appearance to those of the well known Tangerine Orange. It was quite a memorable exhibit of Oranges and Lemons, and one that it would be difficult for any other nursery firm to duplicate.

Hardy fruit was represented by a collection of Apples from the gardens of Mr. R. Montagu Turner at Bedfords, Havering. Besides such sorts as Cox's, Rival and Winter Ribston, of great dessert value, but well known to all who attend the R.H.S. meetings, there were several varieties which are not so popular, though of equal merit, and of these the old-time favourite, Cornish Gilliflower, was of excellent appearance.

Novelties in the vegetable line are scarcely to be expected, and the nearest approach was a goodly collection of Sutton's Variegated Kale, which is quite ornamental when growing and is said to be good eating, though one's fancy would naturally turn to their Extra Curled Scotch Kale.

Royal Horticultural Society's Annual Meeting

WITH such a President as Lord Lambourne any general meeting is bound to proceed smoothly and pleasantly, even if there had been any differences of opinion held by the members on policy. Lord Lambourne creates such an admirable atmosphere of good-fellowship that it was small wonder to find that everyone left the R.H.S. annual gathering with the full conviction that all's well with the horticultural world. The President, however, spoke seriously and with intent on the subject of illicit commissions which, he stated, were within his own knowledge tendered by an unscrupulous minority, a state of affairs which "reflects discredit on all classes concerned."

The only bone of contention, if it were contention, related to the presumed lack of reasonable facilities for reaching the Wisley Gardens. Lord Lambourne explained that a London General Omnibus, which leaves Weybridge Station at regular intervals, will carry visitors near to the entrance and also that the matter was still being considered by the Council.

The suggestion that the provision of a gallery in the Hall would ease congestion by providing for

those who wished to get a general impression of the exhibits met with definite settlement by means of the L.C.C. regulation, which will not permit one.

"Correlative Science" was somewhat of a poser. Many of the Fellows endeavoured, with more or less success, to accept it as an everyday matter, but were obviously relieved when the President confessed that he "wasn't sure he understood what

JOHN FRASER, V.M.H.

was meant." But it is to receive the early and earnest attention of the Council.

Home-grown bulbs are again to come to the front, for the Council have arranged a show of dormant bulbs to be held in the autumn and this is to be followed by a spring show of flowers in 1923. This should be valuable assistance to the already thriving industry.

Mention was also made of the alliance with the National Rose Society and the projected trials of Roses at Wisley, which will perhaps be a step onwards towards a National Rose Garden.

The Treasurer, who seconded the adoption of the report, was most hopeful of the financial future of the Society. He remarked upon the new policy of putting by sums of money to act as an insurance fund for the gate at the Chelsea and other large shows against loss through unfavourable weather, a policy which met with general approval. In speaking of his own resignation, Mr. C. G. A. Nix said he felt that with the increasing financial work the treasurership should be in the hands of a more experienced man than himself and he was of the opinion that in Mr. C. T. Musgrave the Society has found an excellent treasurer. There was no election, as the various nominations did not exceed the vacancies.

The presentation of five Victoria Medals of Honour was an exceedingly interesting part of the meeting. The recipients were Lord Lambourne, Mr. John Fraser, Mr. W. A. Bilney, Mr. Wm. Poupard and the Rev. Arthur Boscawen. The Lawrence Medal was awarded to Messrs. Dobbie and Co. for their exhibit of Tulips at the Hall on May 10 and 11 of last year, and the medal was handed to Mr. W. Cuthbertson.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cucumbers.—The bed of leaves and manure having been prepared and allowed to settle down, small mounds of soil, sufficient in number to receive the plants, should be placed in position to become well warmed before planting is done. Should it be inconvenient to arrange for the bed at present, the young plants must be potted on and not allowed to become stunted, for having been sown early last month it is quite time they were growing freely.

General Work.—When the soil is in a good working condition lightly run the hoe between plants of Winter Spinach, autumn-sown Onions and Carrots, giving the first two a dusting of soot at the same time, removing also any decayed foliage from the Spinach. Where a portion of the Onions are for transplanting it may be done now on to a well prepared piece of ground in rows 15 ins. apart. As different batches of winter greens are used up, push on with the preparation of the ground, so that when wanted later the minimum of time will be necessary in its final usage.

Seeds to Sow.—When the soil is in a workable state Parsnip seed should be sown without delay. A deeply worked piece of land should be chosen, and where this is of a heavy texture choose a stump-rooted variety for preference to minimise deformity of growth. Between the rows of Early Peas on a warm border sow seed of Spinach. Seed of Carrots may be sown on a warm border.

The Flower Garden.

The Spring Beds.—Plants occupying these beds should be examined and all losses made good from the reserve plot. Choose a day when the soil is fairly dry so that the surface of the beds may be stirred a little and chance seedling weeds destroyed.

Hydrangea paniculata.—All weakly wood should be removed and strong growths cut back to stout basal eyes when pruning this plant. The present time is a suitable one for planting fresh positions with the Hydrangea, and should it be the aim of the planter to introduce other plants into the bed the spacing of the Hydrangeas must be arranged accordingly. A spring display may easily be arranged for by giving the bed a carpeting of Polyanthus, Forget-me-nots, &c. A well enriched soil of a good depth is necessary to get the best results from this Hydrangea, and if possible, a good annual mulching should be worked into the soil each spring.

General Work.—Flower beds not occupied with plants for a spring display may be dug thoroughly, working some humus into the soil if thought necessary. Viola stools should be lifted and, after giving what attention is necessary to the site, they may be carefully divided and replanted. In some districts this replanting of the old stock will have to be done on a larger scale than usual this spring owing to the scarcity of cuttings available last autumn. A sufficient stock of Sweet Pea plants should be arranged for. Grow them as sturdily as possible. Should the weather be unfavourable for any ground operations, see that all stakes and brushwood are in order for use among the plants on the borders during the season.

The Hardy Fruit Garden.

Autumnal Raspberries.—These are useful where a long Raspberry season is appreciated, but at present they do not appear to be particularly well known, or, at any rate, very popular. To those first planting this section it must be mentioned that the fruit is borne on the new wood each year, so when pruning, cut the canes down to the ground within a few stout buds. This can be done now, and, if necessary, a much of well decayed leaves and manure given. It is not too late to plant, provided the business is attended to at once.

Fruit Under Glass.

Melons.—The main soil ingredient for the successful cultivation of this fruit is good fibrous loam, to which may be added a small portion of spent Mushroom manure, a little mortar rubble and wood-ash. Whether grown in pots or beds, a firm rooting medium is necessary to prevent grossness of growth, which is oftentimes a forerunner of canker. So arrange the fixing of the plants that when in their permanent quarters the soil immediately around the stems is slightly raised above the remainder.

H. TURNER.

(Gardener to the Duke of Northumberland)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cucumbers.—Growth should be encouraged by keeping the atmosphere warm and moist. Stop the leading shoot and thus encourage the necessary quantity of lateral growths for covering the trellis. Avoid overcrowding of the foliage and, as the fruit sets, thin freely, as over-cropping readily exhausts the plant and tends towards deterioration in the quality of the fruit. When the roots show on the surface add a top-dressing of rich compost and thus add to the vigour and longevity of the vine. Should dull weather prevail at this time do not syringe the foliage. Damping of the walls and paths will suffice.

Sprouting Potatoes.—Seed of early and second early varieties should be examined and placed in shallow boxes to sprout. Everything possible should be done to encourage a slow development of sturdy growth, for if the finest results are to be obtained from the early crop, the seed should receive every attention that can be bestowed on it. When the tubers are allowed to lie in heaps and produce long sprouts that are easily damaged or eventually rubbed off, the seed naturally loses much of its vitality. Give plenty of light after growth is visible, but until then a partly darkened structure is best. In our northern district, May Queen, Midlothian Early and Sharp's Victor are favourite sorts for early work.

Asparagus.—Place another batch of the roots of this popular vegetable in a forcing pit or warm frame so that regular supplies may be maintained. Cover over with about 4 ins. of soil and pack firmly between the roots. Asparagus will force readily in a temperature of from 55° to 60°. When growth appears, spray overhead during the afternoon with tepid water.

Saladings.—Sow turnip-rooted Radishes at regular intervals on a gentle hotbed and, should the weather be frosty, cover the sashes with protecting material as the slightest check at this period causes toughness in the root. A quick hearting variety of Lettuce may also be sown for pricking out in frames later. Weekly sowings of Mustard and Cress should also be made in boxes and placed in a warm vinery, thus ensuring quick and tender growth.

The Hardy Fruit Garden.

Peaches and Nectarines.—The pruning and training of Peach trees or Nectarines out of doors should be no longer delayed, as given a favourable spell of weather the buds will now swell rapidly. Provided the trees received proper attention during the summer and autumn months, very little wood will now require to be cut out, with the exception of any odd shoots that may have to be removed to avoid overcrowding. In carrying out the training, first tie in the principal branches, distributing them evenly over the allotted space, and then lay in the young shoots in such a manner as to give the tree a well balanced appearance. Should traces of scale or red spider be noticed the trees should be cleansed with a dressing of Gishurst's Compound before being tied in. Apply the dressing with an ordinary paint brush, working from the base to the point of the shoot and, in this way, lessen the likelihood of damage to the buds.

The Flower Garden.

Herbaceous Borders.—Any re-arranging of plants in the hardy border should now be carried through, provided the soil is in good, workable condition. In preparing the border work in a generous supply of leaf mould and well rotted manure, as most plants in the herbaceous border are gross feeders. When planting, group the various plants in good-sized masses.

Single Dahlias.—From seed sown now nice strong plants may be had ready for planting out early in June. Sow in pans containing a light, rich compost and germinate in a genial temperature. When the seedlings are about an inch high pot them separately and stand in a warm frame for a period. Guard against the ravages of slugs.

Polyanthus.—Sow in boxes of good sweet soil and exercise patience in awaiting the germination of the seed as at times this is both slow and irregular. Place a piece of dull glass over the seed box, as this helps to keep the soil moist. When the seedlings are sufficiently advanced, prick out into boxes and gradually harden off by placing in a cold frame, finally transferring to nursery lines in the open border about the end of May

JAMES McGRAN,

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock, N. B.

CONSERVATORY AND GREENHOUSE.

Cannas in small pots for greenhouse decoration are not so generally grown as their merits deserve; this, probably, because their cultivation in this way is not generally understood, yet by growing successional batches they may be had in flower right throughout the summer months. If there is plenty of heat at command a start can be made early in January, but where it is not desired to use so much heat, now is a good time to make a start. An average temperature of 50° will suit them very well, allowing it to rise to 60° with sun-heat during the day. For this method of cultivation good strong rhizomes should be selected, using one strong lead for each pot; they should be placed directly into 4 in. pots, potting them on afterwards into the 6 in. size. Use at all times a rich compost, as they are gross feeders. One-third of the compost should consist of dry, well decayed cow manure or old mushroom-bed manure, which will obviate the need for leaf-mould. As the rhizomes are very apt to decay, they should have but little water until they have made some root and have started into growth. When in full growth they enjoy liberal supplies of water and plenty of feeding. Growth should be restricted to one strong shoot, which—if the right varieties are used—should flower when about 18 ins. in height. The following are a few of the sorts that are suited for this particular style of cultivation: J. B. van der Schoot, President Meyer, Alphonse Bouvier, Elizabeth Hoss, Frau E. Kracht, Duke Ernst, R. Wallace, Königin Charlotte, Gaekwar of Baroda, Papa Crozy, Meteor and W. Watson

Tuberoses are again being offered by dealers. When received they should be potted into 4 in. pots, afterwards shifting them into the 6 in. size. If it is desired to force them, they should be placed in a temperature of 65°, plunging them in a bed with bottom-heat at command. They require careful watering until they have made some root and started to grow freely, when the temperature should be increased to 70° or 75°. As the flowers appear they should be removed to a cool house. If it is not desired to force them, they may be grown under much cooler conditions, in a temperature of, say, 50° to 55° or so, for in the south they will grow outdoors during the summer in light, warm soils.

Watsonias are sometimes offered by dealers about this time, and they are very desirable for the cool greenhouse. The most beautiful one for pot work is the white-flowered *Watsonia Meriana* (triflora) Ardeni, which is frequently sold as var. O'Brienii. Four or five corms should be placed in a 7 in. pot. In common with most South African bulbous plants, they only require a cool greenhouse temperature. Very little water should be given until plenty of roots are produced and the plants commence to grow. Well grown examples reach a height of some 3 ft.

Liliums.—As bulbs come to hand they should be potted up at once, since they quickly suffer if left exposed to air. If there is any delay in potting they should be kept covered with moist leaf-soil or fibre. Many species of Liliums are stem-rooting. In potting such, room should be left for a top dressing of several inches of soil. *Lilium auratum*, *L. speciosum*, *L. Henryi* and *L. regale* are good examples of stem-rooting Liliums. *Lilium regale* is a beautiful species for pot cultivation and is easily raised from seed. With good cultivation it will commence to flower when about two years old, as also will *L. sutchuenense* and *L. tenuifolium*; in fact, the use of home-grown plants raised from seed is the only way successfully to grow and to keep many beautiful Liliums. When flowering bulbs are potted they are best stood in cold frames, where the pots should be covered with leaf-soil or fibre. This keeps them moist and does away with the necessity for frequent watering until they have made plenty of root and commenced to grow. If cold frames are not available they may be stood outdoors at the bottom of a wall, covering them with leaf-soil.

Erythrina Crista-galli is a beautiful plant for the cool greenhouse, and a stock of plants can easily be raised from seed at this time. It is also easily raised from cuttings, taken off with a paring of old wood—like Dahlia cuttings—when the shoots are about 3 ins. long. Old plants which have been kept dry all winter should be started in a little heat at this time and will soon give plenty of cuttings from the old woody root-stocks. In dealing with young plants care should be taken not to dry them off too much during winter until they have made a fairly large root-stock. I have seen several batches of young plants lost in this way, through the ignorance of young cultivators.

GIANT
SWEET PEAS

GIANT SWEET PEAS

SPECIAL OFFER for 1922.

Every Seed offered is hand-picked, therefore, every Seed may be relied upon.

The following SWEET PEAS are a very choice selection of the GIANT WAVED OR FRILLED TYPE (four-flowered under good cultivation) representing a wonderful range of colour suitable for garden effect, for cutting in abundance, also superb for exhibition. All strong growers, giving good stems.

- Alexander Malcolm, giant new fine cerise.
- Annie Ireland, giant picotee.
- Brocade, giant rosy lilac.
- Charity, giant crim-on.
- Cherub, giant creamy picotee.
- Daisy Bud, giant pink.
- Hawmark Pink, giant bright rose pink.
- Illuminator, giant salmon.
- Jack Cornwall, V.C., giant rich violet blue.
- King White, giant white.
- Mavourneen, giant rich pink.
- New Buttercup, giant cream.
- Pastel Blue, giant pale blue.
- Prince of Wales, giant rose.
- R. F. Felton, giant lavender.
- Royal Purple, giant bright purple.
- Royal Salute, giant light cerise.
- Scarlet Emperor, giant scarlet.
- St. George Improved, giant coral.
- Tangerine, giant orange.
- The President, giant deep orange.
- Vermilion Brilliant, giant vermilion.
- Wedgewood, giant fine Wedgewood blue.
- Warrior, giant bright maroon.

SPECIAL.—One full-sized packet of each of the foregoing splendid Sweet Peas—a fine range of colour for cutting or show—for cash, 21/-, post free. One half packet of each, for cash, 10/6, post free.

FREE.—One packet of "Mrs. Tom Jones," the new giant four-flowered height blue, will be given free with each order for the above.

FREE.—"The Culture of Sweet Peas," by Henry Eckford, price 3d., given free with each order for the above when asked for.

Write for Catalogue giving details of all the finest Sweet Peas in existence, the Choicest Flowers and Vegetables for 1922.

 Four almond trees in bloom . . .
 What should I ask of God or Man?
 My heart has no more room!

V. H. FRIEDLAENDER.

Secret Commissions.—Last week's "Notes of the Week" were devoted to the consideration of some aspects of the work of the Royal Horticultural Society. This week it may be well to consider some of the points made by the President in his speech at the annual general meeting. Lord Lambourne said that he did not suggest that secret commissions and other illegal practices were more prevalent in connexion with the horticultural trades than with others. With due respect to his lordship's opinion, it is greatly to be feared that he is mistaken. The truth is that horticulture as a profession being the most ill-paid of all, professional gardeners are for the most part either whole-souled enthusiasts, such as the one described in our issue of February 18 (page 81), or men of little purpose and sometimes lesser attainments who have not the moral strength to refuse a bribe. They do not, of course, call it a bribe or even permit themselves so to consider it. Indeed, like the politicians who repeat a lie until they themselves believe it truth, after accepting such "presents" a few times these men come to look upon them as lawful emoluments or perquisites. Nor is this all. They begin to consider that they have a grievance against law-abiding firms who refuse to give these commissions, and point out to their employers what they are pleased to consider shortcomings in their seeds, plants or sundries which would not have been "discovered" had the commission been paid.

An Omission.—It is an extraordinary thing that so common-sense a measure as the Secret Commissions Act should have been placed upon the Statute Book at so comparatively late a date. This deplorable thing has become a custom—a custom to which it is difficult to put an end. Many a man who would scorn to sell old seed—or even to mix old seeds with

new to "use them up"—has said with Hamlet, "I am myself indifferent honest, but yet . . ." I do not see why I should stand by and see a good customer filched away—Commissions Act or no Commissions Act." So we get a vicious circle: gardener corrupting tradesman, tradesman corrupting gardener. If some firm is detected and a case made out, it is almost always against one of the firms mentioned who would fain be honest. The blackest sheep of all are as a rule too artful so to be caught napping.

The Remedy.—This notwithstanding, and despite inevitable hardship to individuals—to those, in short, who break that well known business "Commandment" *"Thou shalt not get found out"*—it is vital that the law as it stands should be ruthlessly enforced. It would be an excellent thing if every garden owner were to impress upon his staff, in plain words, the iniquity of the custom and his own resolution to take drastic steps to cope with the evil should any case come to his knowledge. Beyond that, the remedy lies with His Majesty's judges who, remembering that, like blackmail, this is a most insidious crime and a peculiarly difficult one to detect, should administer the law with the utmost severity.

Rubbish Merchants.—While Lord Lambourne is endeavouring to clean out Augean stables, he might well consider whether there is any con-

ceivable way of bringing within reach of the law the "flat-catchers" or "rubbish merchants" who batten on amateur gardeners, especially novices. Bearing in mind that they cannot hope for repeat orders, it seems wonderful how they contrive to make their advertising pay until one remembers that, unlike the legitimate trader, they have not to depend upon a moderate percentage of profit. Gross profits and net profits are, in their case, separated only by the cost of their advertisements. There is little doubt that some of the worst of these frands might be "laid by" for obtaining money by false pretences were it not for the very natural reluctance of their victims to expose their own simplicity. Readers of THE GARDEN will, for the most part, have little idea of the dimensions of the operations carried on by some of these sharks, as their victims naturally belong to the less sophisticated class—to those, in short, who can least afford the loss.

Once Bitten. the would-be gardener is naturally shy of adventuring a second time, so that, apart from the immorality of the business, these cheap-jacks effectually dissuade many thousands of people from the practice of a recreation which is the high road to good appetite, good health, good temper, good taste and good citizenship.

Easy Access to Wisley.—Another point raised at the annual meeting, and one to which the

President promised the consideration of the Council, was the question of the inaccessibility of the Wisley Gardens. It may be that the Council have figures giving, at any rate approximately, the number of visitors per week throughout the year. If so, they may safely allow for a very considerable increase if better facilities are provided. The question will then arise as to whether it would not be possible on certain specified days per week (or per month) to run at a moderate charge charrs-à-banes direct from some accessible part of the Metropolis. This seems the best starting-point, since most non-resident Fellows visit London at least once a year, while for the vast majority the only practicable route of access, unless in their own conveyances, lies through London.

PERHAPS THE MOST BEAUTIFUL OF ENCRUSTED ROCKFOILS, SAXIFRAGA LINGULATA LANTOSCANA, SHOULD NOT BE OMITTED FROM THE SMALLEST ROCK GARDEN.

THE ROADSIDE GARDEN HEDGE

The advantages and disadvantages of different materials. Is a formal hedge as necessary as the aspect of suburban roads would make one believe?

THE first consideration in dealing with the roadside garden is the material to be used for its hedges. Enclosure is necessary, and is, as a rule, provided for in a practical manner by the builder. Unfortunately, the provision so made is frequently chosen on account of the economy of expenditure involved rather than with a view to getting anything in the way of pleasing effect. Where a permanent fence is provided, such as a wall or close paling fence, the consideration of what material to use hardly enters into the question, as a hedge becomes unnecessary. Where, however, the division between the road and the house has to be a live one, it does. This boundary can be of two sorts, either a closely trimmed hedge or, where room and other circumstances permit, a line of evergreen flowering shrubs left to grow as Nature intended them to do. The first is the one usually adopted to-day, not, I think, because it is the best, but, being commonplace, it is the most obvious suggestion. The idea appears to be to plant something that can be trimmed to look as much like a green wall as possible, hence the material employed is restricted to a few shrubs of which Privet, Box, Yew, Holly, and, in favoured districts, Euonymus, form the staple. These can all be trimmed to form quite solid walls, and where the area is very much restricted this is an advantage. It is also argued that where such hedges are kept closely and well cared for it gives a neat and tidy appearance to a road. It does, but at the expense of interesting variety. Its adoption has tended to make every road in every district look exactly

alike. *Euonymus japonicus*, for instance, is a very fine shrub for this purpose and, where it will grow, one of the best. It has a solid, comfortable appearance, gives a rich note of green to a district, and its glossy leaves allow the first shower to wash off the accumulation of dust that is inevitable in these days of motor traffic. But in seaside districts, where it is used almost to the exclusion of everything else, its deadly monotony gets very tiring. As an alternative there is English Yew—perhaps the best of all hedging materials and certainly the most interesting. It can be kept as solid as a wall if desired and has a truly English note. Your lowland hedges, trim lines of massive green,

suggestive of the pleasures of old Elizabethan houses and smooth alleys for aged feet. Being accused of poisoning cattle, its use by the roadside is deprecated, though why cattle should be allowed to feed on a hedge I fail to see. It will last as long as the house does, and is amenable to the most drastic cutting. It is almost plastic in its adaptability for training into curious and grotesque shapes for those who like such things. Personally, I do not like topiary work and consider it a false use of material, but many people do like it not, I think, because of any beauty it possesses, but

AMONG FLOWERING SHRUBS TO FORM AN INFORMAL HEDGE OR SCREEN VIBURNUM PLICATUM MUST TAKE HIGH PLACE.

because it suggests an association with old gardens. Certainly a road bordered with hedges trained into balls, spires, birds, beasts and all the weird and often ridiculous shapes that are adopted would have a ghostly, eerie sort of effect in the moonlight. It might be considered by some people to be attractive on account of its curious absurdity, but it would never appeal to anyone with a love of the beautiful. Holly is a good country hedge, but is unsuitable to the dusty atmosphere of a town. Not only that, but to cut Holly into rigid lines is to destroy its principal beauty, which lies in its natural growth and berries. Trimmed solid, the glory of its winter colour is lost. Box is a very

satisfactory hedge and possesses all the adaptability of Yew so far as trimming is concerned. It is also delightful in its young green, and strikes a colour note unobtainable in anything else. It possesses with Yew the advantage that it is lasting. Privet makes a good hedge for many years, but cannot be considered a really permanent planting. I think the use of coniferous shrubs for trimmed hedges is to be deprecated. I mean, of course, such things as *Thuja*, *Cupressus* and such shrubs, the beauty of which lies in their grace when allowed to grow as Nature intended them to do. They are unsatisfactory in the garden for this purpose because just when they have achieved the solidity so desirable to the hearts of many people they have a habit of dying at the base, and so untidy holes are created just where density is most desirable.

But is it *always* necessary to have these solid blocks of hedges? Is it not often possible to utilise the beautiful evergreen flowering shrubs in such a way that they will form the necessary screen without being carved into solid walls? It means giving a little more room to the hedge line, and this is often an insuperable objection, but wherever space permits I am sure the road could be beautified by a less rigid treatment of its boundary lines. Many houses have in front of them a low wall, railing or fence. Suppose instead of any of the hedging material hitherto mentioned a little extra space were given to the growing of *Berberis Darwinii* mingled with *B. stenophylla* or one of the other beautiful forms. What a glow of orange and yellow such a road would present in the flowering season! Again, in the autumn with the early frost the changing tints of the foliage would light up the scene. Even in winter they are beautiful, especially when the hoar frost sprinkles the leaves and branches with myriads of scintillating gems. Then they berry, too, some orange, some purple, some coral, and many other tones. They can be pruned to keep them within the necessary compass, without losing anything of their natural grace.

Then there are the Escallonias, constituting another family that will in most districts give seclusion without rigidity of outline. *E. macrantha* and *E. Ingrami* are among the best, and they are evergreen, sufficiently dense, and their habit exceedingly graceful. Where it will thrive, too, the hardy *Fuchsia Riccartoni* makes a wonderful effect as a roadside hedge, but the situation must be carefully chosen and it is not evergreen. There are many other shrubs that are equally suitable, but it involves giving not less than 4ft. or more than 6ft. additional space to the boundary hedge. Whether the garden will afford it is a matter for the owner to decide. But with a flowering tree in every front garden and the hedges treated in the way I have suggested the roads of the average suburb would lose much of the uninteresting monotony they now have. ON RAISING PALMS FROM SEED

There is little difficulty and much interest in raising Palms oneself where a modicum of fire heat makes it possible.

THE raising of plants by an unusual method always holds a special interest, and, it must be conceded, that very few of us have made the experiment of sowing seeds of Palms. In the large nurseries that make a speciality of this class of plants it is the usual procedure, and one may see thousands and thousands in every stage of development, from the single blade, like the first sprout from an ear of corn, to small decorative specimens in 5 in. pots and upwards. Some years ago I determined to obtain some seeds and try my hand and was rewarded by obtaining some remarkably vigorous and decorative specimens that, in a couple of seasons, reached a useful size. First—as to procuring seed; the commoner kinds, such as *Chamaerops excelsa*, etc., can be procured by communicating with one of our larger seed houses, but, for a start, a pound of Dates will ensure a good supply that will grow with great certainty.

I sowed my seeds (which by the way included the Dates) in small pots filled with moist sandy peat in April, standing them over the boiler in a house with a temperature of about 55°. The great point is to keep the soil evenly moist, for the seeds are very hard and take a considerable time to germinate, but any excess of water causes them to decay. Two pots that I treated carelessly in this respect and over-watered became a foul smelling mass, but the remainder came through in time. Probably hard solid seeds like the Date stones would be difficult to over-water, but those that are encased in a shell, like a Coconut, must not be kept too wet.

Give a good watering as soon as sown and thereafter only moisten them. At the same time, equal care must be taken that they do not become really dust dry, for peat in this condition is difficult to moisten through without plunging the pots to the rim for some time, and there is a risk that the roots may just have pushed out and perish. Grow them on rapidly, which means in a moist, shaded and rather high temperature, which is more easily obtained by sun heat during the next six months, after which, if they have to be wintered in an ordinary greenhouse temperature, it is best to harden the growth previously made by admitting more air.

The temperate varieties winter easily in a cool house if they are kept in the warmest position. Do not hurry the potting on into larger sizes, but wait until they are well filled with roots and then give a moderate shift only. Drain the pots with one large crock over the hole and, with a blunt-ended stick, ram the fresh peat down quite firm all round the sides. Too loose potting leads to trouble in two ways: First, the new soil round the edge is apt to absorb all the moisture as it is poured on, leaving the centre dry; whereas, if both are equally solid the whole is evenly moistened. Secondly, the roots push downwards with great force and, when loosely potted, the pressure on the bottom of the pot acts as a lever and lifts the young plant upwards, necessitating potting afresh into a larger pot so as to obtain the necessary depth. Do not attempt to press them back into the pots or the sensitive, brittle growing tips of the roots will be injured and the effect seen in browned tips to the

leaves or even by the loss of the plants. Scale must be looked for, as well on seedlings as older plants, and immediately it is noticed the plants

be cleaned by removing the scales with a sharp-pointed stick and afterwards sponging with clean tepid soapy water. H. W. CANNING-WRIGHT.

ROCK GARDENS AND ROCK GARDENS

Further notes and illustrations on desirable attributes of the rock garden.

ARTHIFICIAL, to more or less extent, compared with the happy example of clearing and planting a stretch of the oolite strata on the Cotswolds, it is a question if any "hand-made" rock garden surpasses the extensive and ever extending area devoted to alpines at the Royal Botanic Gardens, Glasnevin, Co. Dublin. This both in its varied but tasteful formation, and in the beauty, interest and comprehensive character of its planting. It is taken as happily illustrating the value as such as an educational factor for all interested in the subject, and is as largely availed of as it is apparently appreciated. Situated as is the Glasnevin rock garden on undulating ground, giving a more than usual diversity of character, a vast number of species and varieties of an alpine and sub-alpine character have their whims and caprices in soil or site admirably catered for, albeit the local climate is far from being the most favoured in the favoured Green Isle.

That the main object of rock gardening at Glasnevin has not been sacrificed to constructional effect, good as it is, is evident in winding walks and negotiable footways intersecting the whole area in a way that facilities are generously afforded for the minute inspection of every detail by interested visitors. Here, too, of course, as an educational factor, correct and legible labelling of everything in an unobtrusive but permanent manner is a *sine qua non*, and the variety of sites afforded by the formation and natural lie of the ground from sunny, high and dry, to shady, cool, and damp of the low level within the umbrageous influences of ancient Yews comprising the historic "Addison's Walk," gives great scope and almost unlimited character. From the base, too it is not a far cry—but a few feet of green turf, in fact—to the equally interesting bog garden all but on the river's "brim" of the again active and picturesque Tolka. One dares not in but a brief outline venture on a list of the flora of this particular example

PHOENIX PARK, DUBLIN, GLACIAL STONES ARRANGED (?) BY WATER-SIDE.

of rock gardening, nor is late winter quite the time for it. Most are happy in their season of quiet; some, such as the New Zealand *Celmisia*s and tiny gems of the encrusted *Saxifraga* section, and others summed up in "miffy," being modestly protected by bits of glass, although near the afore-mentioned

Addison's Walk a rosy-crimson *Rhododendron* carries its New Year's gift of brilliant blossoms.

The very name moraine seems a sort of shibboleth to the maker of modern rock gardens, but, alas! the making of a moraine often means muddle. One may see, as has been seen, such constructed in or about the rockery which, in its outward and visible sign of a bed of rock detritus, is, on the face of it, what is aimed at—no more, being without its birthright horn of the glacier, an undercurrent of water, or at least copious and sustained moisture derived from gravitation. The very word gives the keynote of character, and given that, interpreted rightly,

THE BOG GARDEN AT ST. STEPHEN'S GREEN, DUBLIN.

your true moraine plant, even should it have to seek its heritage 1 ft. or more below the surface, will, as a rule, be all right; failing that recognition of its birthright, as a rule all wrong. But what a fine feature the moraine adds to the rock garden! Here is a happy example in a town garden (Allesbury Road, Dublin) where rock gardening, commenced a few years since, in a very modest way, now threatens to absorb the whole area; for here, of all phases of gardening, *L'appetit vient en mangeant*. There is a pool on the higher level perennially fed by a tiny artificial supply which has its overflow disappearing shortly after leaving it, being conducted by a subterranean channel which forms the bed of a moraine informally bordering a broken-flagged footway, and extending for some distance too. The moraine by nature, as well as name, is worth having.

Truly Nature is liberal in her suggestions and hints for the rock garden maker and planter, ever and anon showing some examples, too, rather to be kept than copied. For instance, Monte Alverno, immediately overlooking Killiney's lovely bay with its superb bits of natural rockwork fringed with acres of *Cineraria maritima*, and *Veronica hybrida* in bloom the winter through, is picturesquely perched on the granite, advantage of which has been taken by the owner to plant a few alpines in the armpits

of a ponderous shoulder at hand. On the summits of that shoulder is one huge boulder estimated by a qualified engineer to weigh 40 tons, and there it has been poised through the ages, since comfortably settled there by glacial migration. It is Nature in her majestic mood. Relative to this it has been questioned whether the glacial-worn boulders promiscuously placed on the "brim" of the lake in the People's Gardens, Phoenix Park, are not *de trop*, if not actually bad taste. Reconciled as relics of the great ice age, they seem to open up a further, albeit far-reaching, phase of the subject well worth consideration by those who can grasp the bigger and broader principles and possibilities, with the prerogative of a ministering hand.

The very atmosphere of Nature's ways should, in permeating our principles, yield better and broader ideas than is too often found in that perfervid desire to keep all cribbed and confined within depauperated lines and petty limits. In a botanical garden representing a comprehensive collection such may be, probably is, in fact, to greater or less extent absolutely unavoidable, but even there the lesson is taught that Nature labors dotting as she does a vacuum, and plants in colonies. Why the unholy desire of for ever digging up and dividing anything and everything exceeding a given space and a limited space, too?

And, more, why the painful endeavour to variegated the whole area by much mixing and meticulous dotting? Such puerile work is not uncommon in the care and keep of even well designed and otherwise carefully planted rock gardens. The

THE ROCK GARDEN AT THE ROYAL BOTANIC GARDENS, GLASNEVIN.

one objection of a professional friend, and good gardener, too, to the alpine garden is the labour involved in keeping all trim, tidy and neat, which is conscientiously carried out to a fault. It is magnificent, but—it is not rock gardening.

Dublin.

K.

A NEGLECTED CULT

The spring planted bulb and tuber.

MOST garden lovers write out in autumn a list of Narcissi and Tulips and, perhaps, Hyacinth and Freesias, which they require to make gay their houses and beds the following spring. The really expert gardener always makes out another bulb order at this season of the year. Naturally it varies somewhat from year to year, but it usually includes several sorts of Lilies, and it may also include Gladioli, Montbretias, Oxalis, Giant French Ranunculuses, *Dierama pulcherrimum* and *Tigridias*. There is still time to procure bulbs of many species of *Lilium*, though they should be got in now without delay, but bulbs of Japanese *Lilium auratum* (which alone are worth growing) have not long been to hand. For outdoor work the robust form, known as *L. a. platyphyllum* is recommendable, though the typical plant is very

beautiful and not difficult to establish in light soil with plenty of humus, preferable among *Rhododendrons*. A similar place, but with not too much overgrowth (owing to its lower stature) will suit the forms of *L. speciosum*, better known in gardens as *L. lancifolium*, of which the form, *magnificum*, and the similar but later flowering *Melpomene* are the most richly coloured forms. *Album Kratzeri* is a beautiful snow-white form with orange anthers. Similar treatment affords the best chance of succeeding with those beautiful Lilies, *sulphureum* and *regale*.

Few plants make a finer show in the border than the autumn-flowering Gladioli. Where brilliant colour and massed display is wanted the old scarlet *breuchleyensis* cannot be beaten, or if a variety of colour be wanted it may be found among Graff's Canadian hybrids, the giant-flowered *Childsii* or the giant English hybrids of which so many have been sent out of late.

Until comparatively recent years, the garden lover who wanted Gladioli but disliked the rather blatant form of the large-flowered hybrids, had to fall back upon the quaintly formed and oddly coloured *Lemoinei* section. Not so to-day! The ever-increasing family of *G. primulinus* hybrids has added, and is adding, an entirely new interest to an old garden flower. With an entirely new range of colouring, with coyly shaped but charming flowers and inimitable grace of deportment, they are spoken and written of enthusiastically by people to whom the older types were anathema.

Those who wish to grow the new hybrid *Montbretias* should now place their order, as these kinds are not sufficiently hardy to withstand our winters outdoors. Whether they are worth the trouble of lifting each winter is for each one to decide for himself. So experienced a "bulbist" as the Rev. J. Jacob thinks they are.

The forms of *Oxalis* usually planted in gardens are *floribunda* (*lasiandra*) and its white variety *alba*, and *Bowieana* (*purpurata*), especially the last named, which has dazzling rose-coloured flowers and handsome foliage.

A generation ago the tuberous *Ranunculus* was a popular garden flower. Fashions change, it is true, but it is a little difficult to understand why these brilliant and once popular garden flowers should have sunk into comparative obscurity. There is still time to plant the Turhan forms, though they always shrivel somewhat if kept out of the ground, and late-planted tubers seldom do so well as those put in earlier. The month of March is the best time to plant the French sorts, however, and these are very beautiful. They may be obtained to colour or mixed. The colours embrace shades of vermilion-scarlet, crimson, rose-pink, orange, buff, yellow and white.

There is still time to plant the tubers of the Wandflower, *Dierama* (*Sparaxis*) *pulcherrimum*. They should be given a sheltered position in light, well-drained soil. The typical purplish rose form is best known, but there is a very deep purple, almost black form, a beautiful pure white one and a pale rose called *Apple Blossom*. The two last, ordinary folk will find the most attractive. The *Tigridia* is another bulbous plant which is not seen in gardens to anything like the extent it should be. Like the *Dierama*, they like a sunny position and a sharply drained soil. They are not hardy, so must be lifted each autumn. It is unwise to plant them outdoors till March, and they should be stored meanwhile in not quite dry sand to prevent their shrinking. Most bulbs are best surrounded with coarse silver sand, but this particularly applies to the *Tigridias*. These are very beautiful and remarkable plants for greenhouse decoration. If the soil is pleasantly moist at potting time, they should need no water until the "grass" shows above ground.

ANNUALS FOR THE GARDEN

Last year's experiences and their utilisation.

FOR many years, I confess, I grew my annuals as I think numbers of lovers of these charming flowers do still, in any odd border and position in the garden. There were, however, just a few exceptions in the case of several kinds that were ranked as summer-bedding plants. I think it was the more careful cultivation of Sweet Peas—coupled with the fact that annuals had improved so very much in recent years—that induced me to grow all the best of my annuals in quarters by themselves, so that their great beauty in mass form could be enjoyed. Even the different varieties of Mignonette have been grown in beds abreast of each other.

The soil must be prepared very carefully, as a too rich rooting medium would cause some kinds, such as the Lavateras and Marigolds, to grow too tall and require staking, which, unless very carefully done, spoils the general appearance of the plants. Godetias do well in a soil of medium richness, Cornflowers in a rather poor soil, and Larkspurs in a moist, rich one. These few examples may be taken as a guide.

Last year my annual Larkspurs, in poor soil, ceased to grow when the dry spell of weather

came. From June till late in September the plants remained at this stage—six inches high. Then rain came, and early in October they had grown to a foot, and by the middle of the month they were 18 ins. high, bearing lovely spikes of flowers, and the flowering continued till frost came.

A grand dry-soil plant will be found in the Cornflower. Side by side with the Larkspurs referred to, I had Cornflowers; the plants reached a height of 16 ins., then commenced to flower and continued to do so till November, ripening seeds freely and producing thousands of seedlings in the meantime. Some of the latter were destroyed by the hoe, but sufficient were left to form a nice bed several feet wide, and these plants are now robust and six inches high.

The Sunflowers had a struggle to live, but with the aid of several good soakings of water all flowered, producing small, but lovely blooms. A naturally damp soil in a hot summer is an ideal place for the Sunflower. Constant hoeing between rows of annuals in hot weather does far more to keep them going than excessive watering.

I am not dealing with Sweet Peas in these notes, as they stand out by themselves and generally claim special attention. The first error made

as a rule, is that the seeds are sown far too thickly. It is much wiser to harden the heart and determine to drop, say, twenty seeds in a given space instead of a hundred. One may learn a valuable lesson when looking at a solitary Parsley plant and note the vigour, size and quality of leaf. The same impression is made when one examines the solitary Mignonette plant and compares it with the attenuated specimens in the overcrowded bed.

Having decided to be wise at last and to sow the seeds judiciously, the beginner or cultivator of limited experience must carefully watch the resultant seedlings and protect them from the ravages of birds and slugs. When growing in masses a few strands of black thread stretched from small sticks six inches above the soil cross-wise, a foot apart, will prevent loss by birds. A fine dusting of soot renders the tiny seedlings distasteful to slugs and, if not used to excess, stimulates the plants. Around the beds put down unslacked lime and lightly fork it in; do not leave it on the surface, as the slugs work their way underneath.

It is essential to success that early and judicious thinning out of the seedlings be done; but

A BORDER OF ANNUALS—CONSPICUOUS ON THE RIGHT HAND THE GROSS FEEDING BUT STATELY ANNUAL LARKSPURS.

FOR SOIL NEITHER TOO RANK NOR TOO POOR, FEW PLANTS ARE MORE EFFECTIVE THAN THE SATINY GODETIAS.

sometimes enemies do this work too completely, so we must neither be in too great a hurry in this matter nor delay the work too long.

The following hardy and half-hardy kinds should be included in the beginner's collection: Aster, Candytuft, Chrysanthemum, Clarkia, Collinsia,

Cornflower, Eschscholtzia, Gypsophila elegans, Larkspur, Lavatera, Malva moschata, Marigold, Mignonette, Night-scented Stock, Salpiglossis, Ten-week Stock, Sunflower, Sweet Rocket, Virginian Stock, Sweet Sultan, Zinnia and Sweet Peas
OLD TIMER.

TORCH LILIES

Some thoughts on one of the stateliest families of plants which adorn our gardens. A warning as to "incompatibility" on the part of some of them.

BECAUSE even the hardiest species and hybrids of *Kniphofia* are on the borderline of hardiness, or, perhaps, it would be more accurate to say, because the climate of Britain, except in the South and West, is barely sunny enough in the average summer or warm enough in the average winter, it is better to delay the planting of these stately and striking flowering plants until the approach of spring.

The most commonly grown of these remarkable Liliaceous plants is still the long known *K. aloides* (Uvaria), of which the variety *maxima*, *nobilis*, or *grandis*, as it is variously called, is perhaps even now the most striking of herbaceous forms. All the forms of *K. aloides* and most of the many hybrids which have of late years been produced by crossing forms of *aloides* with some of the more tender yellow flowered species are valuable for the mixed border, as their shades of citron and coral are not difficult to arrange without clashing.

As much cannot, alas! be said for the semi-succulent, sub-shrubby (caulescent) forms, of which the flowers have a curious brick-red tinge which agrees with little but their own glaucous foliage. They are remarkable, even handsome, none the less, and may be used satisfactorily in shrubbery openings, forming indeed a very satisfying picture in association with the Sea Buckthorn (*Hippophaë rhamnoides*), for instance. They associate well also, with the Pampas Grasses (*Cyperium argenteum*), with *Yuccas* of sorts and with the foliage of the Day Lilies (*Ilomero-callis*). Of these caulescent forms the best known is *K. caulescens*, and this is, as *Kniphofias* go, quite a hardy species; but the much more recently introduced *K. Northii* is, if less hardy, more handsome, as the flower spikes are finer and have less of the brick-red colouring, while the foliage is broader and even more handsome. *K. foliosa* (*Orontium*), though similar in colouring and length of spike, is quite distinct. It is indeed, more *Yucca*-like in habit than either, a trait which is emphasised still more by that remarkable species *T. Tysoni*, which has leaves 3 ft. or more in length and 3 in. or more wide at the base. Early flowering, as all these sub-shrubby species are, its spikes are freely produced, but they have the daring brick-red

colouring to an even greater degree than *K. caulescens*. It will be understood, of course, that the red colouring in these, as in all other

VERY TYPICAL OF THE GLAUCOUS FOLIAGED, SUB-SHRUBBY TYPE IS *KNIPHOFIA CAULESCENS*.

Kniphofias, fades with age, leaving the dying flowers a yellowish shade.

Coming now to the herbaceous forms, properly so called, anyone who is interested in the various species with a view to forming a collection will be well advised to consult a gardening dictionary. To those, however, who are on the look-out for worthy forms the following are recommendable:

Of the red-flowered kinds *aloides* and its giant form have already received mention, and the variety *præcox* is worthy of notice because of its early (May) flowering. It is not a particularly handsome form, however, and its colouring lacks the richness of *nobilis*. The variety *glaucescens* has rather glaucous foliage and better flower spikes than in the typical form, but it has some of the awkward colouring to which reference has already been made. *Kniphofia Burchellii* is a very beautiful early-flowering species. It flowers a little later than *K. aloides præcox*, but is a much finer and more dignified plant with better shaped, better coloured and more gracious flower spikes. The stems which support the spikes have a richly mottled appearance, caused by spots and blotches of purple pigment, which distinctly adds to their effectiveness. Another imposing and valuable species is *K. Tuckii*, which is June flowering. The heads of flower are quite good, but a little overshadowed by the luxuriant foliage. The yellow-flowered forms, *K. K. comosa* and *pauciflora*, are pretty enough, especially for rockwork, but they are much less hardy than those already mentioned, so, unless in favoured spots, are best left alone; but they have been invaluable to the hybridist.

Seeds of "pauciflora hybrids" are sometimes listed. They flower readily the second year from seed and seem almost or quite as hardy as *K. aloides*, while they retain much of the slender grace and yellow coloration of *K. pauciflora*.

Of many beautiful hybrid forms the following are especially worthy: *John Benary*, which, fairly late flowering, is one of the best and stateliest of the deep red sorts; *Obelisk*, which is a stately form, reaching 5 ft. or so, and golden-yellow in colour; *Star of Baden-Baden*, straw yellow, which, in favourable situations, grows taller still; and the hardy and free flowering, if less statuesque, deep yellow *Lachesis*.

For the rock garden the best species is *K. Macowanii* (syn. *marocana*), a pretty miniature with orange-red flowers. It may well be associated with the *pauciflora* hybrids already mentioned. *K. rufa*, another dwarf red form seems too coarse in stem for its diminutive stature. It is, in short, a dwarf rather than a pigmy.

The quite herbaceous forms are increased fairly rapidly by division an operation which should be carried out after flowering but whilst the ground is warm. The caulescent forms are propagated from cuttings which, under glass root readily enough. It may be necessary to behead the plants to make them break.

Snow is a great enemy to the Torch Lilies, as, indeed in our lowlands, it is apt to be to all plants of a more or less rosetted habit of growth. What would be, if it remained, a warm "blanket" to protect from frost, in our changeable climate too often thaws to snow-broth, only to be congealed in the hearts of the plants by a further change of mind on the part of the "Clerk of the Weather." Such damage may largely be guarded against by tying up the leaves to thatch the crown from damage, and placing bracken around the base of the plants to act as a substitute for the tied-up foliage in withstanding wind-frost. Still, with all our precautions, a hard winter following, as such winters generally do, upon a cold, wet summer will always play havoc among Torch Lilies. Such winters have, fortunately, been very rare of late, and the Red-hot Pokers, as country folk often call them, are so gay and debonair, so obviously aristocrats, yet—for the most part—so amiable and such "jolly good fellows," that their dislike for cold will deter very few from cultivating their acquaintance.

CITRANGES IN IRELAND

BY LADY MOORE.

INCLUDED in Messrs. Thos. Rivers and Son's exhibit at the R.H.S. meeting on February 14 were two of the American hybrid Citranges. It may interest your readers to learn the history of these plants in Ireland. In

February, 1909, Professor Swingle, Physiologist in Charge of Plant Life Investigations at the Bureau of Plant Industry, Washington, wrote to the Director at Glasnevin asking if he "would care to try in your garden located in a part of Ireland where the climate is unusually mild in winter some of our new Citranges." In due course the plants arrived. They are hybrids between the Sweet Orange (*Citrus Aurantium* var. *sinensis*) and *Egle sepiaria* (*C. trifoliata*), the wild Orange of China and Japan. There are four distinct varieties of Citranges — the Savage, Morton, Colman and the Rusk, named after botanists in the United States of America. The cross has been made with a view to impart the greater hardi-

ness of *Egle sepiaria* to the Sweet Orange (*C. Aurantium*). The hybrid shows transitions between the unifoliate leaf (if such it be) of the Sweet Orange and the trifoliate leaf of the other species. It is evergreen like the Sweet Orange—*Egle sepiaria* has deciduous leaves. The flowers are large and fleshy, pure white in colour; a lot of the star shape of the flower of *Egle sepiaria* has been eliminated, thus greatly improving the appearance and effect of the flowers. It is very sweet scented.

The accompanying photographs of the Citrange and its parents were taken by Miss E. V. Miller in the Royal Botanic Garden, Glasnevin, in July, 1921, and that of the fruits in December, 1921. The latter are compressed, spherical in shape,

frequently oblique, about 2ins. in height 2ins. in diameter. Some fruits are quite smooth, others have pronounced furrows running from the base to the apex. They vary in colour from light yellow to deep orange. The fruit of the

TYPICAL CITRANGE FRUITS.

variety Colman is covered with numerous short, stiff, colourless hairs. The trees are budded on the hardy Trifoliate Orange stock. The Plant Bureau at Washington kindly sent plants of each variety to the well known Irish gardens of Sir John Ross at Bladensburg, Kesteven, Co. Down; of Captain Lewis Riall at Bray, Kilmacurragh, Co. Wicklow; to Mt. Usher; to Lord Barrymore's garden at Fota, Co. Cork, and to Glounthanne, Queenstown.

Professor Swingle warmly recommends the fruit as delicious eaten with sugar, an opinion not shared by Messrs. Rivers, who describe it as of a very disagreeable flavour; it is also used in Washington as a beverage like lemonade. Those

grown at Glasnevin when tasted were decided to be of more value for decorative than edible purposes. Although the plants have to be grown against a wall at Glasnevin, they are perfectly hardy in the gardens mentioned. Probably the most effective flowering shrub I saw last year was one of these Citranges covered with its large white-sweet-scented flowers in a border in Captain Riall's garden, Old Conna Hill, Bray, Co. Wicklow, in the month of June.

REMEDIES FOR WOOLLY APHIS

Notes on the habits of a dreadful pest and methods of exterminating it.

AMONG the many pests with which fruit growers have to contend in this country probably few are more common and do more damage than woolly aphis. It may be found to some degree in the majority of Apple plantations, but to a far greater extent in those orchards in which the trees are planted closely and especially where little attention is paid to the important tasks of pruning and cleaning the bark. One may often have noticed old trees in cottage gardens appearing quite white with woolly aphis.

Much may be done to remedy this by summer spraying with such as nicotine and soft soap or a diluted paraffin emulsion, but great care must be taken thoroughly to wet the affected parts, or it will prove to be work in vain.

Probably the most effective method is that of thoroughly washing the trees during the winter with one of the well known Woburn washes, though a solution of 2½lb. of caustic soda to 10 gallons of water will prove to be very effective in destroying the pest.

Much may in this way be done towards keeping the trees free from woolly aphis, but it does not appear to be generally realised that this pest not only attacks the tree above ground, but also the roots. It is highly probable also that a migration takes place from above to below as the winter draws on, and a return migration in the spring. This may be proved quite easily by grease-banding the trees, large numbers of the aphides being seen around the grease band as they ascend the trunk of the tree in spring. Thus much labour may be carried on above ground and be to a great extent wasted if the aphis is allowed to work havoc among the roots.

There is nothing so effective as carbon bisulphide for freeing the roots of affected trees. It should be injected into the soil to a depth of 6ins. by means of a special injector, in for each tree about four places, each about 2ft. from the trunk, using 1oz. of the fluid for each injection in the case of tree-sized trees. Care should be taken that the fluid does not come into actual contact with a root, or harm will be done; the vapour, however, is quite harmless to the roots. When using carbon bisulphide great care must be taken to keep it away from fire, as it is highly inflammable, as well as poisonous. The operation should be performed during the early part of the year, at a time when the soil is comparatively dry, but never after April.

All varieties of Apple trees are more or less liable to be attacked by American blight, as this pest is often called, but those varieties which have a soft bark usually suffer most. Such varieties as Ribston Pippin, Blenheim Orange, Cox's Orange Pippin and Lord Suffield seem to offer least resistance to it, and consequently suffer very badly from its attacks.

SHOWS, AT EITHER END, SPRAYS OF THE TWO PARENTS AND, IN BETWEEN, A FLOWERING PIECE OF ONE OF THE CITRANGES.

Woolly aphid will attack any part of the tree—its roots, trunk, branches, fruit and, in exceptional attacks, the leaves also become affected. The fact that it may persist below ground is a

very important one, for any amount of time and energy may be spent in cleaning and freeing the tree from these insects—all to small advantage if they are "carrying on" below. A. J. POPE.

PEACH AND NECTARINE TREES IN SPRING

To be successful with these fruits the cultivator must watch over the trees very carefully all the year round. At the present time, however, and throughout the spring months, extra care is needed to ensure a full crop of luscious fruits.

WHAT may be termed the amateurs' trees, those that are grown under glass but not forced with strong fire-heat, are now swelling their fruit and growth buds, and the inexperienced cultivator will be anxious to give them the right treatment.

The soil must not be allowed to get dry, and, if not already done, some good, half-rotted, organic farmyard manure should be spread 3 ins. deep on the surface of the soil to cover the main roots. All shoots should, of course, be tied neatly to the wires.

If there are any insect pests, such as scale, left on the trees watch for them every morning and kill them, as, if only a few survive, the trees will be overrun with them by mid-summer, to the disfigurement of the fruits and leaves.

Except in really bad weather, the top ventilators should be opened a few inches early every morning and closed again one hour before sunset; but during the time that the trees are in flower a drier and more buoyant atmosphere must be maintained and a little air admitted throughout the night, too. Twice each day shake the branches to ensure a good "set" of fruits, and also make use of a rabbit's tail or a camel-hair brush.

Very much depends upon the treatment of the shoots and young fruits. In the accompanying sketches *a* shows a single wood bud, *b* double wood buds, *c* and *d* wood and flower buds

respectively; the wood bud is pointed, as shown at *c*, and the flower bud round, as shown at *f*; *g* represents a leading shoot which ought to be retained beyond a fruit on each branch. A young basal shoot and a leading one are shown at *h, h*; *i, i* shoots to be removed; *j* the only fruit-flower to be retained; *k, k, k, k* shoots and young fruits to be removed. The branch *l* shows a later stage of growth, namely, the basal and leading shoots with the young fruit growing freely. At *m* is seen the pistil (embryo fruit), and at *n* the pollen-bearing anthers.

Many branches show young shoots growing between double flower buds. At an early stage of development, where such flowers and shoots are overcrowded, it would help the "setting" process if all shoots and flowers, as marked *o, o, o, o, o, o, o, o*, be removed, leaving a basal shoot *p*, and one fruit *q*, on it with a leading shoot higher up the branch on its upper side. The letters *r, r* show the pistils, surrounded by the pollen-bearing anthers *s*. At *t* the embryo fruit is shown attached to the pistil, and when impregnation is complete through keeping a rather dry atmosphere and good distribution of pollen, the embryo fruit quickly commences to swell. The letter *u* shows the fruit approaching the "stouing" stage after due thinning-out has been done. The fruits when about 1 in. in diameter stop swelling freely for about twenty days; this is the stage when the stones are hardening, and it is advisable to maintain a fairly even temperature, to avoid

THINNING THE PEACH.

any forcing and to apply clear water only to the borders. GEORGE GARNER.

AN ASIATIC CLEMATIS

THE Clematis Farrer 559 exhibited by Mr. A. C. T. Woodward, of Arley Castle, Salop, at the last meeting of the Royal Horticultural Society, is *Clematis macropetala*, Ledebour. The type specimens were collected in Siberia, but apparently we are indebted to the late Mr. Reginald Farrer for its introduction to our gardens. He collected seeds in Kansu, China during 1914, the numbers being F. 315 and F. 559. Mr. Farrer's original description reads, "An Atragene with lilac sepals and a full centre of many white petaloid segments; is a charming thing when scrambling over a rough shrub." It is a deciduous slender climber with biternate leaves, flowering outside during July and August. This is, at any rate, the time it flowered in the open at Kew both in 1920 and 1921. Its nearest ally among well known cultivated species is *C. alpina*. A. O.

CLEMATIS MACROPETALA, WHICH WAS SENT BY THE LATE REGINALD FARRER, FROM KANSU, CHINA UNDER THE NUMBERS F. 315 AND F. 559.

CORRESPONDENCE

THE FORMS OF IRIS UNGUICULARIS.

FLOWERS of what we have at Glasnevin as *Iris unguicularis speciosa* from Dammann of Naples were sent to Mr. Dykes, who, having examined them for swellings or bosses round the top of the tube at the base of the segments, writes: "Your *speciosa* is, I feel sure, not what I know under that name, but an Algerian form. With regard to the name '*speciosa*,' my difficulty is that I do not know that it has any real authority at all. However, I will try and look up this point and see who first described it."

I. u. Imperatrice Elizabetha Mr. Dykes thinks is a Balkan form.

I also sent blooms to Mr. Bowles, who writes: "I feel pretty certain Dammann must have labelled *I. u. lilacina* as *speciosa*. It is certainly my variety *lilacina*. It was, I believe, from Dammann I got mine, so he must have mixed labels in sending it to Glasnevin."

Of *Elizabetha* he writes: "It is evidently a colour form of my *I. angustifolia*, but has more white towards the tip of the fall; it is a very pretty form."

Thus the great authorities! To both of them I am very grateful for their interest and help, but I cannot agree with Mr. Bowles in his slighting dismissal of *Elizabetha*, and I obstinately hold she is distinct in shape, colour of bloom and leaves from *angustifolia*.

To all those readers of *THE GARDEN* who have written me about these Irises, and to whom Sir Frederick Moore has sent bits labelled as we have grown them, I ask that they will watch for Mr. Dykes' naming of our so-called *speciosa*, so that the error may not spread.—W. PHYLLIS MOORE.

HACKNEYED QUOTATIONS.

WILL you suffer a word on a matter which is not gardening, but affects all readers of the gardening Press? I read (or skim) most of the British weekly and four American horticultural papers, and there are certain hackneyed quotations from the poets respecting flowers and gardens which I must have met with about once a fortnight for the last thirty years. Even the noblest sentiment, however expressed, becomes wearisome under such repetition. Wordsworth on Daffodils and "the primrose by a river's brim"—but I need not multiply examples, they will suggest themselves to the most casual reader. Could you not suggest a self-denying ordinance to your correspondents, by which they should bind themselves to omit all reference to a stated list of quotations, for, say, twenty-five years? After this lapse there would be a new generation of readers to which these "chestnuts" would probably come with an air of delightful freshness. You might even go one better, and if Editors have a "Trades Union," put the suggestion on the next agenda and bring the whole journalistic world into line. Do this and "your petitioner will ever pray," etc.—CHARLES E. PEARSON, F.L.S.

[The Editor very gladly seconds Mr. Pearson's appeal. It is often impossible to delete these hackneyed, if beautiful, passages without sacrificing the line of thought of the writer. Will contributors therefore note the objection? There are many beautiful passages, even in the classics, which will not be found in a dictionary of quotations.—Ed.]

A ROSE BY ANY OTHER NAME!

THE so-called Water Violet (*Hottonia palustris*) is a truly beautiful native plant, totally absent or rare in some parts of the country, but common in other districts where, perhaps, conditions are

more suited to its growth. Its common name of the Water Violet is pleasing enough as a name, but, as it is in no way descriptive, the plant might more justly be known by one of its other names, either Bog Featherfoil or Water Milfoil, both of which give a correct idea of the leaves. It has, strangely, been called *Viola aquatica*, and Water Violet is probably a translation, for Dr. Prior in his "Popular Names of British Plants,"

gives no explanation of its origin. By any name, however, it is just as beautiful, and nothing could be more charming than a mass of it in flower, as, for instance, in a slow-running stream. The illustration is from a photograph taken of it growing in the artificial stream that flows by the Botanic Garden at Cambridge, where for a long distance it has taken possession in spite of the cleaning out. The leaves are all submerged, pectinate and in fine divisions, as commonly found in water plants; the inflorescences rising out of the water remind one strongly of an Eastern, tier upon tier *Primula*. Indeed, from this aerial habit it may be surmised that the plant has evolved from a land ancestor. It has some botanical similarities to *Primula*, though still quite distinct. The cultivation of *Hottonia* cannot be difficult, though there may be some difficulty in successful transplantation. It must have mud to grow in and it appears to like slow-running water. The illustration shows the shoots of Mare's-tail rising above the water and Duckweed floating upon it.—R. I. L.

THE CATTLEYAS AND ALLIED GENERA.

ALL who are interested in Orchids must have welcomed the article on page 43 under this heading. There is no doubt that if only the cost of fuel would drop to make it a reasonable price, warm house plants generally would once more become popular. But this important item where glass is concerned does not affect the cost of the cultivation of such Mexican *Laelias* as *L. autumnalis*, *L. anceps* and the various forms of both, which your contributor does not allude to, in the same degree as all those he names, since they succeed better under conditions which are several degrees cooler than what is considered proper for *Cattleyas* and their hybrids. Moreover, I find these Mexican species quite as easy to deal with as any other, and, if anything, more useful. My reason for saying this is that they are in bloom in December and January when, excepting for *Calanthes* and winter-flowering *Dendrobiums*, long stemmed Orchid flowers are rather scarce, while they are as beautiful as any in cultivation. The individual flowers, several of which appear on each spike, the length of which is seldom under 2ft., measure 4ins across; the sepals and petals are rosy—like the colour which has made *Cattleyas* famous, while the tongue-like lip is purple, the throat yellow. Little imagination is necessary to realise how welcome such flowers are

for table-decoration. In fact, those responsible for this matter find them easier to arrange lightly than *Cattleyas*, owing to the shortness of the stems of the latter. There are also some pure white forms, which flower a little later than the coloured ones. These are now at their best and are highly thought of. The cultural remarks in the article referred to apply to these *Laelias*, with this exception. They do best grown in shallow pans at the lighter end of an intermediate house. I grow them in this position in the same house as winter-flowering

THE SO-CALLED WATER VIOLET.

Cypripediums, as I am perhaps fortunate in having a batch of *Cymbidiums*, which acts as a kind of a division to prevent the sun from reaching the *Cypripediums*. Over the *Laelias* the blinds are only drawn to prevent scorching of the leaves. It is remarkable the amount of sun heat these plants can bear providing the roots are kept saturated while active growth is in progress. In fact, flowering in my experience depends upon the plants ripening their growths in the full light. If anyone cares to make the experiment they can grow the plants in shade and they will succeed in obtaining wonderful pseudo-bulls, but they will, if not in the first year, eventually lose the flowering habit, and it will require considerable skill on the part of the grower for them to regain it.—ORCHIDIST.

PRUNING A YOUNG APRICOT.

REPLYING to your correspondent, may I first say that his tree is no longer a maiden, but, apparently, trained for a fan-shaped tree? A maiden tree has but one shoot, and that an upright one, the growth of the graft on the bud inserted the previous spring or summer. A properly fan-trained tree should *not* have a *centre* or *leading* shoot, and I will show how this may be obviated in the case of your correspondent's tree. The centre shoot of the tree in question is 3½ft. long, and it is suggested to cut it back to half its length. The length of the cut-back shoot will then be 21ins. This in my opinion, is too long. By leaving it this length a break of young shoots could not possibly be secured the following spring at the base of the cut shoot, with the result that

the base of the shoot for possibly 1ft. in length would be left permanently bare of foliage and of flower-buds—a serious fault in a trained tree. I should cut this centre shoot to within 1ft. of its base, cutting to a bud on the outside of the shoot and afterwards encouraging the same bud to grow outwards instead of upright in order that it may form a side shoot rather than a central one. On the opposite side of the shoot I should encourage another of the buds to grow into a second side shoot, say, 6ins. below the top of the shoot, both the shoots to be encouraged to grow to their full length during summer and autumn. It is these shoots which go to furnish the main branches of the trees. Your correspondent will find that most of the other buds remaining on the cut shoot will break into growth and form shoots. We do not want too many of these. Four will suffice, two below the lower shoot and two between it and the higher shoot at the top. Select the four strongest and rub off those remaining. The four buds remaining should have their centres pinched off as soon as they have attained a length of 5ins. to prevent their growing any higher. The same short shoots at winter pruning should be cut back to within two buds of their base in order that they may form groups of fruit-spurs throughout the length of the stems of the main branches. So much for the centre shoot of your correspondent's tree.

Of the side shoots there are two on one side of the tree and one only on the other, each about 2ft. long. The tree will become lop-sided if the balance is not soon adjusted. To bring this about I suggest that each of the three branches be cut back to within 6ins. of their base, not shortened by one-third their length, as suggested by your correspondent, and, further, that two new shoots be taken in spring from the single shoot, one from the top bud and one from a bud at the side 5ins. lower down, and further that one shoot only be taken from each of the two shoots (these, of course, from the top buds). Doing this by the autumn will bring about the right balance of shoots. Other buds which will break into shoots in spring at the base of the cut-back shoots must be reduced to four by rubbing off those not wanted, and the centres of those remaining be pinched off as soon as they are 5ins. high to prevent their growing higher and at winter pruning be cut back to two buds of their base as advised in the case of the centre shoot. These technicalities of pruning are difficult to make plain to a beginner. I hope, however, they may help your correspondent over his difficulty.—OWEN THOMAS, V.M.H.

A NATIONAL DAFFODIL SOCIETY?

I APOLOGISE to "Somers" and to all concerned. He was right and I was wrong in my entire under-estimate of the crowd the proposed Society will at once "rope in." He limits the officials of the National Daisy Society to 130. There is every reasonable hope that this moderate number will at once be reached or exceeded by the National Daffodil Society. One of the prime movers in the matter told me that, as a beginning of necessary machinery, its committee would be formed by an amalgamation of the existing committees of the R.H.S. and the Midland Society, *with additions*. These two bodies already number 82, and the 130 is, therefore, well in sight. I would suggest that, as new clubs enrol their first members without entrance fee, so the new society should be popularised by putting the first 100 members on the committee. A wise man once said to me that the best committee is one of two members with one absent, but then he was quite an old-fashioned person. Of course, I was immensely flattered by having a leader, so to speak, of THE GARDEN all to myself (January 28). But I assure the Editor

that I am by no means alone in my criticism of the scheme. There are people who write to the papers and also people who do not. And, after all, I have done no more than humbly suggest that it may possibly be a waste of time and energy to make a loud and probably expensive to-do in order to obtain, under a new name, what we apparently have already. My own belief is—and I have advanced some reasons—that this cult of the Daffodil is an intimate and highly specialised study which will never be popular, with or without brass bands, as Messrs. Jacob and Co. reckon popularity. But Heaven forbid that I should sit longer on their safety-valves; I am old and detest explosions.—G. H. ENGLEHEART.

I HAVE been a reader of THE GARDEN for many years, but am getting tired of the continual dragging of coat tails by writers, who appear to consider themselves and their especial fads the only matter of consequence to gardeners. Lately someone called the Daffodil the "National Flower of Wales." I thought that was the Leek! I beg to suggest an International Onion Society, which should encourage the growth of all classes of that succulent from the lovely flowering Alliums to the toothsome pickled Onion and the fragrant Chives and Chibbles or Spring Violets.—ORIUM.

THE PERSIAN CYCLAMEN AS A WILDING.

THE bulb of this Cyclamen was brought home in a small tobacco tin to Hampshire by an officer. The day he started on his return home for leave in March, 1917, he dug it up close to the

NOT INFERIOR IN GRACE TO THE BEST STRAINS IN COMMERCE TO-DAY!

line then held by the British Army from Jerusalem to Jafia, across the Judean Hills, near Hadattia. It bears this year twenty-six blossoms at one time.—E. M. B.

POTATO NOMENCLATURE.

I THINK it is time that someone who knows the "ins and outs" of Potato nomenclature should state plainly the position to-day of varieties like Midlothian Early and Duke of York, and as the matter has been raised in your columns by H. Saunders, I send you a few lines which you can put in your "W.P.B." if anyone who knows better sends along a contribution on the subject. Duke of York was raised by William Sim and

sent out by Daniels Brothers in 1891. Midlothian Early was raised by G. M. Taylor and sent out by Scarlett in 1905, and by Dobbie, who bought the half of Scarlett's stock, in 1906. It was claimed by the raiser, and also by Scarlett and Dobbie, that it was an improvement on Duke of York. Mr., now Sir Matthew Wallace, Bart., grew it at Terreglestown, Dumfries, among his 195 acres of early Potatoes in 1906, and it was reported in *The North British Agriculturist* that "there was no difficulty in detecting the difference, the Midlothian Early being decidedly nicer in shape of tuber and heavier in the yield." The position then was that there was a difference; it may only have been the difference which is nearly always associated with a true seedling of similar character to its parent. The intervening years and the handling of the varieties by hundreds of growers and merchants who saw no difference between the two varieties, and whose interest it very often was not to look for one, resulted in their getting inextricably mixed, and the only possible thing to do to-day is to bracket them as synonyms, and, in addition, The Faithful and New Success can be added to the group of York synonyms. Exactly the same thing has taken place in other groups. Synonyms of Abundance and Up-to-Date exist in great numbers. They may all have been true seedlings at the beginning, but to-day they are sold for one another quite freely for the same reasons that I have stated in connexion with Yorks and Midlothians. In your footnote to Mr. Saunders' letter you say "there must be more strains than one of the variety." I put it another way—there are more areas than one in which the variety is grown for seed. *Verb sap*.—W. CUTHBERTSON.

I WONDER if you would care to give, or to elicit through the correspondence columns of your informative and entertaining paper, the truth, the whole truth, and nothing but the truth, concerning Duke of York and Midlothian Early Potatoes? Are these two separate and distinct varieties or is the Duke (improved, perhaps) masquerading under a Scots title? Some time ago I grew Duke of York. His Highness yielded a fair crop of medium-sized tubers. He was not sufficiently disappointing to adorn the garden black list, nor good enough to form the subject-matter of a letter home to mother. Last year I plunged with Midlothian Early. The results were an abundance of unusually large, delicious Potatoes, minus chats. Of the two varieties, in my experience, Midlothian Early of 1921 was a Prince of Potatoes compared to Duke of York, say of 1915. The real dilemma is this: One great firm of seedsmen flatly and dogmatically states that Duke of York and Midlothian Early are synonymous; another great firm will accept your money for either or both sorts; a third firm offers one variety only; and a fourth the other variety only. Can you tell me, please—are the two sorts one and the same stock, or not?—A. C. MARSHALL.

THE POMEGRANATE.

MR. AVRAY TIPPING'S interesting note in THE GARDEN of February 11, page 65, brings to memory that many years ago I saw the Pomegranate blooming beautifully on the wall of Swyncombe House, in Oxfordshire; the brilliant scarlet flowers made a striking display. The peculiarly bright colour, where there is a profusion of bloom, is quite arresting; but though I was privileged for twenty years to visit occasionally these beautiful gardens, so finely kept by my old friend John Daniells, I never remember seeing the Pomegranate make much of a show again; possibly the summer when it flowered so well may have been a very hot one.—J. P., *Cheltenham*.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Onions.—Provided the ground is in good working order the sooner seed is got in the better. Select for this crop land which has been thoroughly well done, and endeavour by treading and raking to bring the soil to a fine tilth for receiving the seed. If a dressing of wood-ash and soot can be arranged for so much the better. The drills should be about 15 ins. apart, and, after the seed has been lightly covered, firm and finally rake lightly over.

Tomatoes.—A sufficient amount of seed should now be sown to provide the main summer fruiting batch for both inside and outside. Allow the seed to germinate in a temperature of about 61° and endeavour to grow the young plants at all times in a light position. There are so many "best" varieties on the market that the most practical solution of what to grow is, grow just those varieties which give good results, whether old or new.

Early Marrows.—With improved varieties to choose from of recent years early Marrows are becoming increasingly popular, and they are most certainly a valuable addition to the kitchen list. Where a heated pit can be spared or a hot-bed arranged with frames upon it, little difficulty will be experienced in obtaining a few early fruits. A fairly rich soil is advisable, but the growth should not be made in excessive heat and moisture. Sow the seeds singly in 6-in. sized pots and then pot on again if their permanent position is not ready, so as to avoid a check.

Seeds.—It is not necessary yet to make large sowings of the Brassica family, but care should be taken that a sufficient supply of early Cauliflowers, Brussels Sprouts, Cabbage, Lettuce and the early autumn Broccoli plants are all thought of. The young plants of Cauliflowers, etc., already pricked out or awaiting treatment should be carefully aired and watered, the aim being sturdy, well rooted stock which when planted out will grow away freely.

The Flower Garden.

Open Spaces. which are admirably adapted for the sowing of annuals, often present themselves in the woodland garden or in the lesser dressed portions of the grounds and fronts of shrubberies. As it will soon be a suitable time to sow the seed, the ground should be prepared in readiness. There are quite a number of annuals which will give a fine display in such positions. To mention a few worthy of note we have the annual Poppies, Lupins, Larkspurs, Clarkias and Sweet Sulphurs. Where it can be arranged for bold drifts of Poppies or Lupins to have a background of some sort the effect is better.

Tuberous Begonias required for the summer bedding must be started now in gentle heat. Where a slightly heated pit, with movable lights, can be given up to them it may be so arranged that no further trouble as to another move will be necessary, as when the plants and the weather merit it the lights can be taken off. A light compost is the best for starting the plants in, and this can be placed from 5 ins. to 8 ins. in depth upon a firm ash bottom, spacing the bulbs out according to size from 6 ins. to 12 ins. apart. An occasional light syringing will be found beneficial in encouraging growth in its early stages.

The Hardy Fruit Garden.

Outdoor Figs.—Any winter protection which has been given these trees may now be removed and the necessary pruning carried out. Select strong, well ripened shoots for laying in, and unless it is necessary to shorten them to fit into their allotted places do not cut them back. Do not leave the branches too closely together, as it is particularly essential that the sun and air have a free access to this fruit. A few well placed growths should annually be encouraged from the base of the tree.

Fruit Under Glass.

Early Figs.—Where these are obtained from pot or tub-grown plants it is essential that the stopping of the young growths is thought of in time. From three to six leaves is ample growth for the first pinch to take place. It may be necessary, in dealing with plant-out trees, to allow more freedom growths required for extension.

H. TURNER.

(Gardener to the Duke of Northumberland),
Albany Park Gardens, Guildford

FOR NORTHERN GARDENS.

The Kitchen Garden.

Parsnips.—Sow seed of these profitable and nutritious roots now. Choose a day when the ground is dry and in good workable condition. Parsnips revel in a soil that has been deeply dug during the autumn months and thrown up roughly to be benefited by the mellowing influence of wind and weather. Irregularly manured ground tends towards coarseness and forking of the roots. Prepare a fine seed-bed and sow in shallow drills 18 ins. apart. Immediately the plants are visible run the hoe through between the lines. This not only keeps down weeds, but aerates the soil and ensures that vigorous growth so essential to plant life during the seedling stage.

Brassicæ.—Seed of Savoys, Cauliflowers, Curly Kale and mancrop Cabbage should now be sown for general planting. Sow on a light sunny border, in drills 1 ft. apart. A further sowing of Brussels Sprouts should also be made to supplement those that are being grown in frames. Protect the seed-bed from the depredations of birds by netting.

Peas.—Make a further sowing of early sorts in rows 5 ft. apart. This allows for another sowing of early round Spinach being made between the rows.

French Beans.—As the days lengthen, this ever-popular vegetable becomes easier to force and crops more heavily. If beds are not available, then in forcing pits; the seed should be sown in sun pots. Use a mixture of light loam and leaf-mould, and allow about five plants to the pot. A sowing may also with advantage be made along the front of Tomato boxes, and in this way a good catch crop may be obtained without detriment to the Tomatoes.

Horseradish.—Unfortunately, in many gardens this is a neglected plant, but where choice sticks are in demand opportunity should now be taken to replant the bed. Lift every particle of root before replanting and dig in a generous quantity of well decayed manure. When replanting, select straight sets of medium size and about 10 ins. in length, with crown on top. Divest these of all side roots and dibble into holes about 12 ins. deep. Place a quantity of the old roots in the reserve border for immediate use.

Onion Sets.—Plant these in rows 12 ins. apart and 6 ins. apart in the rows. Scatter wood-ash or burnt refuse on the surface and rake in when preparing the ground. Good-sized bulbs may be raised from sets in gardens where failure results from ordinary sowing.

Fruit Under Glass.

Vines.—In establishments with only an early and a lateinery the latter should now be closed down and allowed to start without undue forcing. Spray the rods over during the afternoon and damp the paths and border surface.

The Orchard House.—Maintain an even temperature in this structure, keeping a watchful eye on pots of Peaches or Nectarines that may be in flower. Assist the setting of these by hand fertilisation.

The Flower Garden.

Lobelia fulgens.—Roots of this effective Lobelia which have been wintered in frost-proof quarters should now be divided and placed in a warm pit for a period until established, when they may be transferred to a cold frame until required for planting in the open.

Salvia patens.—Tubers of this exquisite Salvia should now be started into growth. Dibble the tubers into boxes containing a compost of loam, leaf-mould and sand, placing the boxes in the genial warmth of ainery or hot-bed.

Geum Mrs. Bradshaw.—Sow seed of this delightful perennial now and so obtain well grown plants for filling beds or replenishing groups in the herbaceous border during the autumn months. Sow in a well drained seed-pan and germinate in a warm greenhouse, pricking out in a cool frame when the seedlings attain reasonable size.

Pruning Buddleias.—Prune Buddleias of the variabilis type back to within a few buds of the old wood. B. Colvillei, also a rampant grower, flowers better if not too severely cut back; while B. globosa may be kept trim by having the more straggling growths cut away.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.)
Goodham, Kilmarnock

CONSERVATORY AND GREENHOUSE.

Ventilation.—As the sun increases in strength more ventilation will be required in plant houses, and at this time great care is necessary, as bright, hot spells accompanied with cold winds are frequent, and much harm may result from a careless and unintelligent use of the ventilators. Air should always be admitted on the sheltered side of houses, and every possible care should be taken to avoid draughts, for they are much more harmful to plants than a low temperature. Every plant house should be fitted with bottom ventilators opposite or slightly below the level of the hot-water pipes, the cold air passing over the pipes gets slightly warmed as it enters the house. Except in very severe weather, a little air should always be left on the bottom ventilators. Conserve all possible sun-heat by shutting up houses as soon as possible. By this means a material saving in fuel may be effected.

Clivias are very useful for greenhouse decoration, and may be successfully cultivated with very little heat. They may be had in flower over a fairly long period if a considerable number of plants are grown, as flowering may be hastened if successive batches from a cool house are introduced into a slightly higher temperature. As the plants pass out of flower such as require it should be repotted. Before being repotted the plants should have all the soil washed off their roots, at the same time carefully removing all decayed roots, etc. When the plants are dry, pot into suitable-sized pots. This requires great care, as it is no easy matter to work the soil in among their thong-like roots. After potting stand the plants in a house with a temperature of about 50° to 55°. At this stage they should be given very little water until they make fresh roots, and heavy syringing should be avoided, as the strap-shaped leaves carry too much water into the pots, thus making the soil too wet and probably sour before the new roots become active. When the plants are well rooted and in full growth they enjoy abundant supplies of water at the root.

Begonias of the Lorraine type should now be giving plenty of suitable cuttings. The cuttings should, of course, proceed from the base of the plant. Stem cuttings never make good plants. Some growers contend that the best plants are produced from leaf cuttings. Personally, I have never found any difference when proper cuttings were used, and cuttings have the advantage of being much faster. When stock is scarce leaves may, of course, be used with advantage. Begonia socotrana, one of the parents of Begonia Gloire de Lorraine, should be more generally grown. It forms peculiar resting buds, and towards the end of this month or beginning of April is time enough to start it in a warm house. This Begonia is also the parent of the beautiful race of winter-flowering Begonias raised by Messrs. J. Veitch and Sons. As regards their propagation and cultivation, I hope to deal with them at the proper season. In the meantime stock plants of them require careful management. Very little water should be given at the root; on the other hand, they should not be dried off too much. Begonia nite, or so-called "rust," is a great pest, and to many other plants besides Begonias. It, however, can easily be totally prevented or held in check by using Campbell's Sulphur Vaporiser. A few applications in the course of the season is a sure preventive.

Boronias are old favourite greenhouse plants, but at present are seldom cultivated except by a few growers for market work. Boronia megastema with its delicious fragrance is a great favourite and has been in flower for some weeks now. This plant, in common with many other sweet-scented plants, has a very sober dress, the outside of the petals being purple brown, the inside yellow. There are only two other species commonly cultivated, one is Boronia elatior, with rosy carnation flowers, and the other B. heterophylla, with rosy red flowers. Both the last-named species flower about April. They are all natives of Australia, and are propagated as most hard-wooded greenhouse plants are, by short twiggy shoots inserted in pots of sandy peat. The pots should be covered with bell glasses and stood in a house with a temperature of some 55°. Plants that have finished flowering should be cut back and stood in a house in a temperature of 55°, where they can be kept close and moist until they start into growth. They may then be potted on or left until they have just finished their growth.

J. COULTS

Royal Botanic Gardens, Kew

OBITUARY

SAMUEL TISDALE.

ANOTHER link with the past is removed by the loss of Samuel Tisdale, who died on February 14 in his eighty-ninth year. He started his career as Rose propagator with the firm of Messrs. Richard Smith and Sons of Worcester. He afterwards entered the service of Messrs. Barr and Sugden (now Messrs. Barr and Sons) as manager of their nursery, Garrett Lane, Tooting, where the firm's famous collection of Daffodils was grown and where they conducted their seed trials, and remained with the firm some twenty-five years, retiring in 1907, when Messrs. Barr and Sons were establishing their nursery at Surbiton. He then went to live with his son-in-law at Bryanston Square, assisting him in his florist business. Samuel Tisdale was always a very active and intelligent gardener, and was closely associated with the cultivation of the famous collections of new seedling Daffodils raised by Edward Leeds and William Backhouse, which were acquired by the late Mr. Peter Barr. He was a well known figure at the old flower shows of the R.H.S. held at South Kensington, when Messrs. Barr were exhibiting their new Daffodils in Day and Martin's blacking bottles.

Strange to say, he was buried on Saturday, the 18th ult., at Streatham Cemetery, which occupies the site of Barr's old nursery, where for so many years he was cultivator of the many plants which were grown there.

Royal Horticultural Society's Examinations.—Prospective candidates are reminded that entries for the examinations for the National Diploma in Horticulture close on March 4. The dates of the examinations which are for members of the gardening profession only are: Preliminary and Final written examinations, Saturday, May 27. Practical examinations at the R.H.S. Gardens, Wisley: Preliminary, June 27 and 28; Final, June 29 and 30. For syllabuses and entry forms apply to the Secretary, Royal Horticultural Society, Vincent Square, Westminster.

Charity Concert.—On February 16 the twenty-third annual concert organised by Geo. Monro, Limited, in aid of various charities, was held at the Queen's Hall. An excellent programme was provided, which included an organ recital and some excellent music rendered by the band of H.M. Grenadier Guards. Last year the Committee made the following grants to charities: £10 10s. to the Gardeners' Royal Benevolent Institution, £3 3s. to the Royal Gardeners' Orphan Fund, £5 5s. to the Wholesale Fruit and Potato Trades' Benevolent Society, £6 6s. to the Royal Surgical Aid Society, £6 6s. to the Charing Cross Hospital, £3 3s. to St. Dunstan's, £3 3s. to the London and Home Counties Benevolent Fund, and £2 2s. to the Covent Garden Lifeboat Fund.

Ideal Home Exhibition.—On Wednesday March 1 Princess Alice opened the Ideal Home Exhibition at Olympia at 3.30 p.m., when admission was by invitation only. The building was opened to the public at 5 p.m., but each other day, until March 25, the Exhibition will be open from 10 a.m. to 10 p.m. at a charge of 2s. The varied display embraces a vast working demonstration of newest devices and inventions for houses and gardens of all sizes. The large annexe holds a most beautiful collection of gardens designed by the Queens of Holland, Spain, Belgium, Norway and Rumania, Queen Alexandra, Princess Mary, Princess Alice, Lady Patricia Ramsay and four children of the

Royal house. To view these gardens an extra charge is being made, of which the whole proceeds will go to the Middlesex Hospital.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

IRIS HOOGIANA (North Notts).—This Iris does best when planted early in November and lifted when the foliage has died down—usually in July. The roots should be stored in dry soil throughout the summer and autumn until the planting season comes round again.

HYACINTHS FAILING (Timplae, Newcastle, Staffs.).—The cause of your Hyacinths flowering down in the crown is either excessive heat, putting into heat before thoroughly rooted, or possibly they were allowed to go dry at the root before being taken inside. Any one of these mistakes would account for the trouble.

MIGNONETTE PLANTS DYING (E. A., Holmes Chapel).—The diseases to which Mignonette is heir are few, and none seems to apply to the trouble stated by our correspondent. On full consideration of all the circumstances, we are inclined to the opinion that the dying of individual plants in the beds is probably due to injury, such as accidental bruising by a hoe. This would account for the appearance of damping off at the collar with large plants. The cultural detail followed by our correspondent is admirable and deserving of better results. If the trouble occurs during the coming season we should like an affected plant or two, with roots attached, for examination.

TREES AND SHRUBS.

SCREEN TO HIDE FOWL-RUN (C. B. W., Byfleet).—As far as we can visualise our correspondent's garden, it would seem that a Yew hedge would be altogether too stiff and formal for the purpose. Scotch Pines or Larch, planted irregularly 5ft. apart to form a screen rather than a hedge, would probably make at once the best windbreak and at the same time obliterate most effectively the fowl-run. The Beech hedge suggested should be better than one of Yew, but it would be wise, if possible, to avoid a hedge at all.

HEDGE OR SCREEN IN PARTIAL SHADE (C. B. W., Byfleet).—The amount of shade, and more particularly the amount of the drip mentioned by our correspondent, are rather important. It would be unwise to trust valuable hybrid Rhododendrons to such a site, but R. ponticum should succeed. Holly or Laurel or, unless the drip is very considerable, Berberis stenophylla would also answer.

MISCELLANEOUS.

WATERSIDE PLANTING (C. B. W., Byfleet).—If our correspondent gets a Weeping Willow for the canal-side site he mentions, he should take care that he does not obtain a specimen grafted in the head; such are never satisfactory. Golden Willows grow rapidly and would be very satisfactory in such a situation. Whether Siberian Irises would flourish depends upon the dampness of the site. They like plenty of moisture. Given this, some of the Candelabra Primulas would be admirable. P. japonica, P. Bulleyana and P. polycranta are recommended, especially the last. If our correspondent cares to send further details, particularly as to the area of moist soil, we could no doubt render further assistance.

BOOK DEALING WITH THE WIRING OF FLOWERS (E. T., Kent).—We are not aware of a book which treats on the subject of wiring natural flowers used for wreaths, bouquets, &c., nor does the subject seem to be embodied in any work on floral arrangement. It is not an intricate business, and we suggest that if instruction is needed most florists would give one or two practical lessons by arrangement for a moderate fee.

ARTIFICIAL MANURES FOR THE FLOWER GARDEN ("Withy").—Our correspondent may use bone meal (finely ground) or guano for the flower garden at the rate of about 2 oz. to the square yard, or where lime is present, a mixture of five parts superphosphate, three parts sulphate of ammonia and two parts sulphate of potash, at the same rate. Where small areas are concerned the extra cost of some of the well known proprietary manures is compensated for by the trouble of mixing such things as the above. Bone-meal is less active and more lasting in its action than the others mentioned.

NAMES OF PLANTS.—C. S. C.—Hedera Helix var. narniorata.—G. B. W.—Impatiens Sultanii.

CATALOGUES RECEIVED.

- Charlesworth and Co., Haywards Heath, Sussex.—Orchid List, beautifully illustrated in colour.
- C. Engelmann, Saffron Walden, Essex.—Perpetual-flowering Carnations.

Herbaceous Plants & Rose

PLANT NOW to secure a succession bloom throughout the Summer and Autumn. We offer **Strong Flowering Plant** (not Seedlings or Rooted Cuttings) of the following at specially reduced prices:—

	Per doz
Achillea ptarmica plena, double white, free flowering ..	7
Aconitum Fischeri, delightful porcelain blue Monkshood ..	7
Anchusas, Dropmore and Opal, well known Borages ..	7
Asters (Michauxias-Païries), in great variety, tall and dwarf, early and late ..	7/6 to 10
Campanula persic. corulea grandiflora, tall blue Chimey-flower ..	7
Chrysanthemum maximum (white Spasta Daisies), in variety ..	5
Delphiniums, in many varieties, all shades of colour ..	7/6 to 10
Erigeron Quakeress, pale French grey Fleabane ..	6
Geum Mrs. Bradshaw, double scarlet bloom ..	5
Gaillardia grandiflora, old-fashioned Blanket-flower, golden and scarlet ..	5
Heucheras, in many varieties, pink, rose and crimson ..	5
Heleniums, in variety, including Riverton Gem and Beauty, yellow and copper coloured Sneezeworts ..	7
Helianthus (Perennial Sunflowers), in many varieties ..	5
Iris, broad leaf Germania types, best named sorts, all shades of colour ..	7/6 to 10
Monarda Cambridge Scarlet, most useful crimson-scarlet Bergamot ..	7
Montbretia crocosmiflora, strong clumps, orange-coloured bloom ..	5
Nepeta Mussini (Catmint), excellent for edging, continuous lavender-like bloom ..	5
Pæonies, in great variety, all colours ..	9/- to 10
Potentillas, double and single florists' varieties, all shades of yellow—red to deepest crimson ..	5
Rudbeckia Newmanii, dwarf yellow Cone-flower, blooms in early autumn ..	5
Rudbeckia Golden Glow, taller, yellow variety ..	5
Solidago (Golden Rod), in several varieties ..	5

Half-dozens at Dozen Rate.

Carriage paid upon all orders of 10/- and upwards for Cash with order.

COLLECTIONS.

We offer the following Collections selected by us from the above-named plants:

Collection A.—12 good varieties ..	7/6
" B.—24 ..	14/-

Each plant distinctly named; carefully packed; carriage paid.

ROSES.

We still hold a good stock of British-grown Roses leading Hybrid Tea varieties. We offer the following special Collection:

Collection C.—12 Hybrid Teas, all distinct to name ..	16/-
---	------

Carriage paid for cash with order.

JAMES BACKHOUSE & SON, Ltd
(Dept. C),
The Nurseries, YORK

FIVE Million Yards of strong STEEL WIRE (25 S.W.G.), black enamelled, on neat reels 1 mile each, 10/- per mile. Also **One Million LABELS** of hard compressed fibre, with string to almost indestructible; can be tied or nailed on anything. Bag of 500 for 5/-, or 1,000 for 8/-. The above are Government surplus and invaluable to gardeners and others. Cash with order; see carr. paid to any address in U.K.—**F. BARNE BRAND & Co., 3, Victoria St., Westminster, S.W.**

THE Ideal Home Exhibition, now proceeding at Olympia, is exceedingly interesting to everyone interested in economy, whether of construction or upkeep as applied to the home. To the gardener and garden-lover, however, interest centres in the annex, where are situated the "Queens' gardens," of which we have heard so much. They are assuredly worthy of eulogy as representing the most ambitious effort in garden construction at an exhibition ever attempted in Britain. Beautiful as these gardens are, however, and useful as are the lessons they teach to every garden-owner, one feels that a better corollary to the model houses shown in the exhibition would be full-size or half-size representations of tasteful arrangements for an ordinary small to medium sized suburban or country house. That most practical of idealists, the great Ruskin, writing of another sort of Queens' gardens to those on view at Olympia, says: "Suppose you had each, at the back of your houses, a garden, large enough for your children to play in, with just as much lawn as would give them room to run, . . ." Alas! that in this twentieth century there should, in so many cases, still be need to suppose such a thing. Alack! and alas! that, where the garden plot is provided, it is so often put to little use, either practical or artistic.

Garden Photographs.—Many readers of THE GARDEN have but small gardens. The great majority of readers, it is safe to say, have grounds which, compared to the big gardens attached to equally large estates, of which so many are to-day being broken up, are quite small. Many of these smaller gardens, there is no doubt, have real beauty. Pictures of such would be very helpful to fellow-readers. The views in large gardens, which, for want of better, are often used to illustrate the points of articles, though they give the idea recommended, are hardly so useful to the man or woman with limited space at command as would be views showing such ideas translated, in a limited space, into actual fact. If any readers have such photographs by them, they will perhaps send prints, accompanied by any relative particulars, with a view to publication.

Their name and the address of the garden need not be published if they would rather they were not. The size of the picture is not of much importance so long as the prints be quite "sharp." Glossy paper prints are best, preferably on silver printing-out paper, but this is not essential. Accepted prints will, on publication, be paid for at the usual rate unless a wish is expressed to the contrary.

The Mouse and Vole Plague.—The numerous correspondents who have enquired where they

can purchase the Colin Pullinger balance mouse-trap referred to in correspondence as effective against both voles and mice, even in the rock garden, will be glad to hear that it is manufactured wholesale by Messrs. Duke, Waring, Crisp and Co., 139, Wardour Street, W.1, and obtainable through any ironmonger. It is desirable, if the ironmonger is not a stockist, to give him the makers' name.

Push On!—With the season of general growth approaching apace it is time that all deciduous planting were rapidly brought to a close. Such things as Rhododendrons, Yews and Hollies may successfully be transplanted in May, so that, where work is in arrears, they may be left until last. The May planting fetish is, however, if not dead, at any rate rapidly dying. It is to-day generally allowed that the earlier the planting can be carried out the more successful is likely to be the result. Really early planting—the best of all—was quite out of question this planting season owing to the parched condition of the ground. The results are noticeable enough in gardens to-day. Herbaceous plants are, speaking generally, hard to kill, but every week which now elapses, before planting is finished, will depreciate to some extent the sum total of effect in 1922. The same applies with equal force to roses, at any rate as regards the first crop. A good second crop of blossoms may be obtained from trees carefully transplanted—not from a distance, of course—even in June. The last week in May and the first two weeks of June are probably, of all the year, the best times to transplant specimen conifers which must be removed but which have not been recently transplanted. Provision must, naturally, in that case be made for copious waterings should the season prove droughty.

A New Lawn-Mower.—Visitors to the Ideal Home Exhibition should not fail to see the new "J. P." lawn-mower on a stand in the annex. This is at any rate an engineer's job with its sun-and-planet gears and SKF ball bearings, remarkable alike for the ease of its adjustment and the speed transmitted to the cutting cylinder. Should it carry out in practice all the makers claim for it, it should become popular.

CLEMATIS MONTANA. ALL CLEMATISES MAY NOW BE PLANTED.

THE SUBURBAN GARDEN IN WINTER

The writer shows how the too common dearth of winter flowers may be overcome.

WORKING through an average suburb in winter it is difficult to realise that a very large number of the inhabitants have a genuine love of gardens and flowers. An occasional yellow Jasmine, a great many specimens of Pyracantha (often with very few berries), and now and then a Laurustinus bush are practically all there is to attract the eye; even these are seldom seen in full vigour. In summer most of the little gardens are gay enough, but in the dull months, when the need for cheerful sights is greatest, little is to be noticed but a superabundance of evergreens producing a most dreary effect. The causes of this winter dullness appear to be fourfold: (1) want of knowledge of many of the most suitable plants; (2) lack of proper preparation of the soil and simple cultural care; (3) fear that the garden will not be so gay in summer if plants are included which are not effective at that season; (4) the unsupervised jobbing gardener.

A visit to Kew Gardens on a fine day in midwinter would be very enlightening to many people. In addition to the above-mentioned Jasmine, Pyracantha and Laurustinus, the easiest grown winter-flowering plants and berry-bearing shrubs are probably Hamamelis mollis (a fine yellow-flowering shrub), Daphne Mezereum (both white and pink), Rhododendrons dauricum, mucrolatum and praecox (all much alike, pink), Garrya elliptica (evergreen), Chimonanthus fragrans, Berberis Bealii, Lonicera Standishii, Erica carnea (in various shades of pink as well as pure white), E. darleyensis or mediterranea hybrida, Iris unguicularis (in various shades of blue or purple and also white), Clematis calycina (a climber), Petasites fragrans (the Winter Heliotrope), Skimmia japonica, Cotoneaster rotundifolia, C. microphylla, Erandis hyemalis (the Winter Aconite), Cyclamen Cornu-albernicum, Narcissus

Bulbocodium, Crocus Imperati, C. Sieberi, Helleborus niger (the Christmas Rose) and Galanthus nivalis (the Common Snowdrop).

Most of these thrive best if left undisturbed for several years at least, so that it is essential to prepare the ground very thoroughly before planting. If possible, trench it deep, adding as much good sweet loam and well decayed manure or leaf-mould as possible, also road grit if the soil is very heavy. Most plants would also appreciate

a dressing of lime (omit this for Rhododendrons, Ericas and Hamamelis). If unable to have the ground trenched, at least dig large and wide holes for the shrubs, and add to the soil as above. With the exception of the bulbs (which should go in as early as possible in the summer), plant in March, or April. Be very careful to plant firmly, stake if necessary, and see that no fatal draught can blow upon the position chosen. No further attention will be needed except to make sure that the plants do not suffer from drought in late spring and summer. Give a thorough watering now and then, and protect the roots from the scorching rays of the sun by a mulch; or better still, for a small garden plant low-growing things, such as Violas or London Pride, which will serve the same purpose. No pruning will be required,

Narcissus and the Christmas Rose. The Hamamelis, Daphnes and Ericas like an open place, also the Crocuses. The Garrya, Chimonanthus and Lonicera like the protection of a wall, but this is not essential. A considerable amount of thought will certainly have to be given to the subject if the summer show of flowers is not to be affected. But there are several plants which add greatly to the beauty of the garden at that time which will appreciate the companionship of these winter flowers. It is only necessary to mention the splendid family of the Lilies to be at once reminded that branches of shrubs will protect them from those late frosts which so often check their growth, and also shade their roots from the burning rays of the midsummer sun. Only the Iris and Ericas will be found to object to a little crowding and consequent shade in hot weather.

Lastly, if it is desired to have a flowery garden in winter, it will be necessary to see that the gardener knows just where the bulbs are, and that he does not dig there precisely at the time that they are beginning to shoot. He must also give up his habit of pruning everything as hard as he can (when he frequently shears off the very shoots which would produce the flowers and berries if left to do so). If he also understands the art of summer mulching, all should be well.

A. E. W.

THE PATH THROUGH THE HEATH GARDEN.

For the suburban garden, an arrangement such as this gives a maximum of display in a minimum of space.

unless to remove some awkward straggling shoot.

Clematis calycina will need a warm wall or fence or a sheltered corner. Iris unguicularis needs a south aspect at the foot of a wall, also very poor soil with lime or builders' mortar rubbish. Petasites fragrans spreads very rapidly, and should be relegated to an out of the way corner or used to carpet a shrubbery border under evergreens. The Rhododendrons like partial shade, as do the little Cyclamens, the Snowdrops, Aconites, the

The Value of Heaths for Winter Effect

THERE is, perhaps, no race of plants so valuable for winter effect as the hardy Heaths. Not only is there one variety (*Erica darleyensis*) which habitually flowers in the dead of winter and several others which are interesting at that season in that they are smothered with half-swollen buds ready to open at the advent of spring, but almost every species and variety gives at that season an effort of furniture. They have an interest, too, even to the eye of the veriest amateur—an interest which needs no previous communion with nature to make it manifest, as is unhappily the case with much winter beauty of the countryside. The varying habits of growth lend variety. There are entirely prostrate forms, such as *Calluna vulgaris*, *Foxii* and *pygmaea*, and from them by degrees, as it were, through plants of the habit of *darleyensis* and *carnea* to quite erect-growing kinds, such as *mediterranea*, *lusitanica* or more especially *stricta*. The gradation of foliage colouring is not less wonderful. The range even of the common *Ling*, *Calluna vulgaris*, runs from the clear bright green of *alba Serlei* to the almost black hue of *Alporti*, which makes the clear greens seem the brighter by contrast. There are in addition golden and bronze leaved forms of *Ling* which give a much to be desired note of warm colour when days are short and dark. If to these we add the varying forms of the different species of *Erica*—*vagans*, *Tetralix*, *cinerea*, *mediterranea*, *lusitanica*, *stricta*, *australis* and *arborea*, with foliage differing widely in size, arrangement and texture and in innumerable shades of green—some bright, some dull, here blackish, there glaucous, now covered with buds for next season's crop of blossoms, now lit up with the warm brown of masses of last year's seed-pods—it is easy to understand why, even to the uninitiated, the Heath garden always affords interest even in the dead of winter.

THE GARDEN GATE

The artistic value and practical worth of the unpretentious gateway, with hints on its setting and maintenance.

WHAT a difference the entry into the garden or into some portion of it makes in the appearance of the whole! Its lay-out surely demands our most careful study

and wisest thought. It is a question that is of even more importance in the small or medium sized place, than where there are acres of grounds in which a single item is sure, to some extent, to be swallowed up by the design as a whole. In a restricted area the value and decorative effect of a fine entry or gate is accentuated and appreciated to its utmost. Such gateways vary enormously in character and construction and, while all are good in their place and when suited to their surroundings, care should be taken to see that they harmonise with their accompanying conditions. A fine old open ironwork gateway, with its typical brick piers, round stone balls and large pots overflowing with Hydrangeas, for instance, is eminently suited for proximity to the house or other buildings, but placed in the middle of a garden, it would lose its meaning and appear foolish unless, indeed, it were cut through a wall leading to the kitchen garden. Even then it always appears to me a pity not to have used it nearer the house.

An open gateway always has a great charm as one approaches it, in that it permits but a partial view of that which lies beyond and so keeps you guessing at a partially revealed mystery, enticing and urging to further exploration. Wooden gates of substantial structure, fitted in under an archway of some gay climber are most effective and, generally speaking, as cheap to construct as possible, though for absolute permanence, there is nothing to equal iron, kept well painted. The wooden gate, however, is a gate of great charm, especially if in the natural colour of the wood from which it is made, and simply varnished to preserve it. Paint in any form is simply unthinkable in connexion with a gate that is to be really artistic. One recoils in horror before the vision of the "garden green" coating with which some folks are willing to coat their trellis or woodwork in the garden—a green that wars violently with every known tint of nature. Better far, if painting is the only course, to employ a darkish neutral brown that has at least the merit of looking inconspicuous, though there is nothing to beat the tones of the natural wood either stained or varnished.

A gate must be sufficiently high to suit the purpose for which it is placed in its position, but

should never be carried higher than necessity demands. A gate—breast high—with an arch of similar wood above it, either in the fashion of a lych-gate or simple arch with Clematis, etc., rambling over it, is effective, so that it consists with

A PLEASING GARDEN GATEWAY.

adjacent architecture, both when seen from a distance and when one leans across the top and gazes upon the garden beyond. Never let it be forgotten that a gate—like everything else—should have some reason to justify its existence and, therefore, ought to be kept shut. The simpler the latch the better: just a latch that drops into a staple on the opposite post being all that is necessary. Nothing is more annoying than a latch that is difficult to open or a gate that "sticks." Of all types the gate that swings itself shut and closes by a simple latch and staple is the best and most readily re-adjusted if the post should sink.

Much can be done, when fixing the gate, to ensure its shutting behind those who enter by giving a slight tilt to the posts so that the balance of the weight of the gate tends to swing it closed. A spring is always a great assistance, but these in time become weaker and fail to shut the gate unless combined with the tilt I have described. It is not desirable to accentuate this tilt too strongly or the gate will close with a crashing bang that, quite apart from its nerve-shattering effect, is bound in course of time to disturb the setting and to cause the post to work loose.

For wooden gate—the best type of hinge is one that spreads across the face of the gate and is held by several screws rather than a butt hinge which is let into the post and one edge of the gate. Rolling hinges, springs, latches, etc., should be regularly done, especially in winter, as the more easily these glide the less jar there will be to disturb the setting. W. H. CANNING-WELCH.

The Adaptation of Plants to Environment

Illustrated by the Gentianella and its Alpine cousins.

THE old *Gentianella* of English gardens was introduced into England at the end of the sixteenth century. Its characteristics differ from those of the wild type, having been adapted to the mild climate.

I brought some with me from England and cultivated them forty years ago, near other types, to study their adaptation. I made thus some interesting observations upon them. I took up the study on the suggestion of the late Professor Romanes of Oxford, who was the scientific heir of Darwin. He induced me to try the culture for observation purposes of types nearly allied, but coming from different countries. We began this in our botanic garden at the Linnaea in the Valaisian Alps (5,800 ft. altitude). But there was no possibility of close observation so far away, so I tried here at Florare. I took all the different acaulis forms—*angustifolia*, *alpina*, *Clusii*, *dumosa*, and *Kochiana*, together with the garden plant *Gentianella*. Mrs. Montgomery of Blessingbourne, Ireland, sent me once a photograph of a bed she had in her garden which approached perfection. Millions of flowers of *Gentianella* crowding one another in an ordinary garden bed. It was such a sight that nobody here would believe that the picture was not taken in the high Alps. Even in the Alps I never saw anything like it. So I hoped to grow it so at Florare, but such results are impossible. I hasten to say, in our Continental climate.

There are five different species of acaulis type. The French botanist, Perrier de la Bathie, published a note on the different alpine kinds in our Bulletin for the protection of plants* which my late friend Sir Henry Yorke, translated into English; he gave the description of *G. angustifolia*, *Clusii*, *Kochiana* and *alpina*. *Kochiana* and *Clusii* are the anatypes, the one of the granite-calciferous, the other chalk loving. The three others are, or seem to be, indifferent as to lime.

G. Kochiana Perrier = *G. excisa* Koch = *G. latifolia* Gr. Godr. is the plant of the granite mountains. It grows in the Jura too and in other limestone countries, but only in decalcified soils in which rain has washed away the chalk. It has large, broad, thin, light green leaves; they are marked by five big veins, rarely only three, and are lanceolate-oblong, never pointed, oval, rounded, paddle-shaped; the calyx segments are short and flat and never adhering to the corolla, but rather recurved and separated by truncated sinuses. The flowers are dark blue and rather dull violet, with five large green spots inside. It is the more difficult for us to cultivate because our water is too chalky. The plant is not at all stiffly upright and forms dense patches not more than six inches across.

G. Clusii Perrier is distinguished by its leaves, which are lanceolate, pointed and coriaceous, by the lanceolate sepals which are adherent to the

* Bull. ass. p. 17, 74, Geneva, 1884. Baron Perrier de la Bathie, translated into English by Sir Henry Yorke, Greenwich, 1897.

corolla and in nowise contracted at the base and are separated by sharp sinuses. The flowers are not so large nor so open, but of a good, deep, very brilliant blue, with the lobes of the corolla shortly rounded, on a short stalk often bearing two short, pointed, dark green, opposite leaves. The plant is generally small, building up dense tufts of dark and shining foliage. It grows on the rocky, sun-kissed slopes of the Jura and of the limestone Alps between stones and gravels. Its culture is very easy and, like *Kochiana*, it never runs. (Synonyms: *G. G. coriacea* (St. Lag.), *firma* (Kern), *vulgaris* (Beck).

Quite different are the two stoloniferous kinds. *G. alpina* (Vill.) is a creeping little plant forming on the slopes of the Alps (granitic or limestone), and of the Pyrénées,† and Sierras of Spain, large carpets of bluish grey-green leaves in small rosettes; the leaves are small and incurving and the flower is without any stalk, quite stemless, so that botanists think it is the true *acaulis* of Linnæus. The flower is rather small, but of a good blue and opens widely. It grows only on dry pastures in full sun. I found on the Pic du Midi (Pyrénées) a form with pure white flowers. The albino *Kochiana* is fairly common, but I never found a white *Clusii* nor *angustifolia*.

G. angustifolia (Vill.) = *sabauda* (Boiss.) = *occidentalis* (Jakow) = *grandiflora* (Lam), is the king or the queen of them all. Nothing can give an idea of its beauty when shining above the paths or in the grass of the Alps of the Dauphiné or in the Pyrénées.† I found last year at the base of the Mont-Aiguille one of the most beautiful things

I ever saw—and I have been all over the Alps. It was on the slope of the big road coming from Chichiliane to the station at Cleilles (on the line Grenoble to Venness); from afar we saw the brilliant gay green slope covered with that rich carpet. I said, "What kind of Periwinkle is that?" believing it to be a *Vinca*. The ground was covered with it; then we saw the dried flowers of *Gentiana angustifolia* with unripe seeds. What a glory! No words can give the impression we had there. The plant is of very stoloniferous character, creeping everywhere and increasing as well as does Periwinkle. The leaves are narrow, sometimes linear, very long and with one, rarely three veins. The flowers are very large, of a good sky blue and borne on a long stalk, sometimes Sims. tall; they are perfect in form. The cup is widely open and inside there are five green spots. It forms large tufts of grass-like foliage, sometimes 3ft. broad! A friend of mine has made with it quite a lawn. The culture of it is the easiest possible, and I think it was originally the *Gentianella* which has altered in character under centuries of culture.

G. dinarica (Beck) = *Rochelii* (Kern), is to be found in the mountains from Herzegovina to Bosnia. The plant is not caespitose, has deep blue flowers, without any spots inside, with broad, pointed, bright green leaves, long and narrow calyx segments, drawing to a sharper point. The flower is very large, but not so large as *angustifolia*. Its culture here is easy.

Floraire, Geneva.

H. CORREVON.

† It grows only in some parts of Dauphiné and here and there in the Pyrénées.

DECIDUOUS TREES IN WINTER

BEING so fond of trees as I am, I suppose I ought to count it a misfortune not to possess any of my own except a few picturesque old Apple trees, which, though desirable and satisfactory as far as they go, supply no equivalent for the variety in form and character of our many deciduous woodland trees. This privation, however, does not make me so unhappy as one might think, because, though I have no timber of my own to potter about and among, I am free, when the humour takes me, to use the grounds and park of Carabas House, the country residence of my excellent neighbour, Baron d'Yvetot, where the planting has, for generations, been done with an eye rather to picturesque effect than to profit. I am well aware that there are persons to whom my sentiments and likings in respect of trees must seem questionable, for, though to me a tree is a tree in any one of the four seasons, it is most especially a tree in the dead season of the year, when you see it divested of the superincumbent wrapping of foliage, which, though interesting of course, and beautiful, as tasteful drapery invariably is, serves, nevertheless, as drapery so often does, to hide a multitude of essential details. It is only, I think, when you see a tree in its unabashed nudity that you can get at the core of its character—for only then can you see, naked before you, the scheme on which Nature has designed it. Take, for instance, my own Wych Elm. I call it mine, holding that it belongs to me as much as to anyone else, and perhaps more; for do I not, year after year, travail in fear that, next time I pass that way, I shall find it cut up into logs: an emotional purgatory, I am very sure, not within the experience of the person who has, *de jure*, the power to do with this tree what he will? And what, I ask, constitutes real, as opposed to legal and merely nominal ownership, if not such labour as mine of the soul and the

affections? My Wych Elm, as I have every moral right to regard it, stands near the gate of a neighbouring farm, and close to a turnpike, along which I have occasion to pass, summer and winter, at intervals. In summer, I will not deny it, this tree is a magnificent dome of foliage; and yet not a dome, neither, in the way of the rotunda of St. Peter's or St. Paul's, for it is not a single dome so much as an accretion of domes, one billowing into another, but all of a joinery so architecturally perfect that—unless you happen to be in a motor 'bus or other non-stop vehicle—I defy you to pass by the tree in the month of June without stopping to wonder at the lush richness of its masses, and to note, with whatever feeling for art you happen to possess, those swellings and depressions (so many hills and valleys you might call them) of green light and purple shadow; an effect, if not actually invented by Rembrandt, at any rate used by that artist to its permissible limit, and, since his time, abundantly copied by Nature, sometimes, perhaps, with a stronger emphasis of chiaroscuro than an art-critic of discriminating taste might think altogether advisable. But fine as the Wych Elm of June unquestionably is, what is it to the January tree, when you see the bark, the warty bole, and the branch-spars in their naked simplicity, with no ornament but their native strength and symmetry, when, also, looking further aloft, you note the tracery of the drooping and interlacing twigs projected against the winter sky like a Moorish pattern on a wall of the Alhambra? It is then you really see *the tree*. What you see in summer, as Teufelsdröckh would assure you, is only the millinery.

I wonder whether there is in the English language, such a word as "twiggy" (collective of "twig"), whether it occurs, for instance, in the Oxford dictionary, of which, unfortunately, I have not a copy by me to consult. I hope not,

because I should be more than gratified to go down to posterity as the inventor of this desirable and necessary vocable. "Twiggy," a possible paragraph in the next edition of Dr. Murray's dictionary may run, "collective of 'twig,' on the analogy of 'greenery,' first used by 'Somers' early in the twentieth century—the characteristic system of twigs or terminal branchlets, which, during the period of hybernation, serves to distinguish one genus of deciduous trees from another." Those to whom a tree is anything at all must have noted how each genus—Oak, Ash, Elderberry—is characterised by its twig-pattern; in short, by its "twiggy." Anyone who cannot identify trees in winter-time by a glance at their twig system, may possibly, when he sees a tree, know that it is a tree and not a camel, but as to any really intimate knowledge of trees he has not yet reached even the alphabet. I modestly disclaim for myself that knowledge of trees, valuable in its way, which is acquired through the dissecting microscope. At the first tree we came to you would very likely floor me if you asked whether the tree in question were diœcious or monœcious. I should probably reply by asking what you meant. And when you had explained—"Oh, yes," I should say intelligently, "I see what you mean. Hollies are diœcious, because, while one individual takes his ease, the other bears the babies." But, for my part, I do not anatomise my trees too curiously. My knowledge is of the surface and empiric, not of the recondite order. I just look at a tree-top and say: "Yes, that is a Larch, or a Chestnut, or an Ash," as the case may be. Then, again, there is the bark—or, perhaps, I should say "barkage," on the analogy of "leafage" (meaning foliage)? The bark is as much a matter of interest and distinction as the twig, though I do not myself find the characters here quite so easy to read as those of the twigs. You see, the furrows and convolutions are so endlessly intricate. Only the other day (to be precise, it was February 10), the frost making profitable work in the garden impossible, while the sun shone with the brilliancy of August and the east wind cut like a thousand knives, I bethought myself of the stillness and shelter of the Carabas woods and park, until something like a hunger took me to see, against such a spotless sky, the various woodland trees in all the rich intricacy of their "twiggy." No sooner thought than done; but when I had wandered all the afternoon, much to my heart's content and enjoyment, through those soft pastures and arborous glades, I came away humiliated to think that I had made several mistakes in bark-reading; that I had, more than once, taken one bark for another which it somewhat resembled, failing to perceive my mistake until I glanced aloft at the "twiggy." Scotland Yard will tell you that each human being bears an unforgeable signature on his finger-tip, by which he may be identified though he hide himself among a thousand. Equally may each kind of tree, among a multitude of genera, be known by its distinctive bark-print, if only you have the skill to read what is as plain as if it were typed in great primer. Certainly the bark-script was not on this occasion always so plain to myself as it ought to have been. But that is nothing to the point; it only shows that I have not yet altogether mastered the art of reading Nature's finger-prints. Of course, there are barks which the most arrant dunce in trees cannot mistake, such as the smooth grey of the Beech, the white satin of the young Birch, the smooth olivaceous cuticle of the Aspen, the greenish grey of the Ash, and the nut-brown, stippled and varnished bark of the Hazel and the young Alder. But the bark varies in texture with the age of

the tree; and it is when trees attain a certain age, and, as is the way with age, put on various asperities and corrugations, each after its kind, that it requires experience and observation to distinguish at a glance the sign-cortical of one tree from that of another; for this differs not merely in trees of different genera, but even in trees of the same species at different ages. Take, for instance, the case of the Birch. The young and adolescent Birch has the silvery-white bark which gleams so cheerfully against a background of

Scots Fir or Holly. The bark of the aged Birch, on the other hand, is scored with pits and furrows of a depth and ruggedness such as you will hardly find exceeded on the trunk of an old Oak or Elm. But, however scarred and rough aged trees may be, each has its own corrugation pattern, the essential difference of which no words are subtle enough to describe. Only the camera or the hand of the observant artist can register those frequently similar, yet endlessly different, reticulations and convolutions. SOMERS.

The Vinery: General Hints on Culture

AS enquiries as to the best treatment for Vines are often received, I am writing these few hints for the benefit of fellow readers of THE GARDEN. As the cost of fuel is a great consideration, the present time is quite early enough for starting the Vines into growth. Started now, very little fire-heat should be required, except in cold, wet weather.

Assuming the Vines have already been pruned, all loose bark should be removed and the rods well washed with a reliable insecticide; the glass and woodwork should be thoroughly cleansed and the walls lime-washed. A clean start makes all the difference later in the season.

If the borders are inside the house, a good soaking with tepid water will be necessary when the house is started. As many amateurs utilise their vineries for other plants, care must be taken not to get the border in a sodden and sour condition, as this and extreme dryness at the roots are the chief causes of bunches shanking.

A temperature of 45° at night will be high enough to start with, allowing for a rise of 10° or 15° during the day under solar heat.

The Vines and all bare surfaces should be well syringed two or three times daily, according to weather conditions.

Old Vines usually break freely, but young rods should have their ends tied towards the bottom of the house to ensure an even break. Disbudding should be done as soon as it can be seen which are the strongest growths. If there is room for extending the rods, a well placed shoot should be tied in for a leader. They should have their points removed, so that when they have finished extending there will be 6ft. of growth. This will strengthen the future rods. The laterals on these leaders should be stopped at the fourth or fifth leaf, according to the space available. The fruit-bearing laterals should be stopped at two leaves above the bunches, and the sub-laterals at the first leaf, unless there is a blank space to fill, when these may be allowed to make a few extra leaves. Stopping of the shoots should be done regularly each week, then the Vines will not receive a check by removing any quantity of foliage at one time. The chief point is not to overcrowd the foliage, as one well developed leaf,

fully exposed to sunlight, is worth six small, weak ones.

If the Vines are in a healthy condition, they will require their second watering about eight weeks from starting. Give them a thorough soaking with tepid water and liquid manure. This will carry them over their flowering period.

VINES GROWN THICKLY ON THE SINGLE ROD SYSTEM AT ST. PETER'S VINERIES, GUERNSEY.

When the Vines are in flower, a night temperature of 65° should be maintained, allowing 5° higher for all varieties of Muscats, although I have seen even Muscat of Alexandria set well in a temperature of 60°.

By keeping the atmosphere of the house drier during the flowering period, and giving the rods a shake several times daily, the varieties Black Hamburgh, Foster's Seedling, Alicante, Appley Towers and Madresfield Court all set freely, but Cannon Hall, Alnwick Seedling, Lady Downes and Muscat of Alexandria are sometimes shy in setting. The best way to ensure a good set of these varieties is lightly to spray them with warm soft water at 9 a.m., using an Abol syringe for this purpose; afterwards draw a rabbit's tail over the bunches very lightly at midday, and all will be well.

Surplus bunches should be removed as soon as it can be seen which are the best shape; a medium-sized bunch should be retained in preference to a long, straggly one. The number of bunches to be left on each rod will depend on the strength of the Vines, taking care not to overcrop, or the berries will be small in size and lacking in colour when ripe.

Thinning of the berries should be done as soon as they are the size of Peas, thinning them out well from the centre, especially late varieties, as a berry getting wedged in the centre of the bunch will often cause decay. The operator must be careful not to touch the berries with head or hands, or they will be permanently disfigured.

When thinning is completed, give the border a sprinkling of an approved Vine manure and a good mulching of thoroughly rotted cow-dung, and well water it in. It is advisable to leave a little top ventilation on for a few nights, to avoid damage from the ammonia rising from the dung.

Treatment, from now until the berries commence to colour, consists in keeping the house well damped when necessary. A thorough damping three times daily in bright weather will keep the Vines healthy. Should a spell of cold wet weather set in, keep a little warmth in the heating apparatus and keep less moisture in the house.

If the Vines are growing strongly, a thorough soaking of water should be applied once each month until the Grapes are ripe; then, if it is necessary for the bunches to remain on the Vines for a long time, the border should be kept a little drier, or the varieties Foster's Seedling and Madresfield Court are liable to split.

As soon as the berries commence to colour, open the ventilators both top and bottom, night and day, opening them wide on warm, bright days, as the warm, fresh air improves the colour.

If red spider or thrips attack the foliage, sponge the leaves at once with a solution of soft soap and flowers of sulphur. Mildew can be kept down by applying sulphur to the affected leaves.

When the Grapes are all cut, the border should be watered with liquid manure, and this should be repeated, as necessary, until the leaves have ripened and fallen, so as to have well ripened wood for producing the crop in 1923. C. H. W.

Young and Old Vines

Hints on the treatment of the new shoots.

VINES, when in fairly good health, grow rapidly and, if the new shoots are not duly attended to, and in a proper way, they soon become a tangled mass and the crop of Grapes, to which the anxious cultivator has looked forward, is far from satisfactory.

Grape Vines, to be a real success, must be very carefully treated all the year round, but much depends on the work done during the spring months. The expert knows exactly what to do, but the beginner does not; to such these brief notes and the accompanying sketches will prove helpful.

The young Vine, when planted late in autumn, or soon after Christmas, is usually cut back to the desired height—generally 1ft. to 2ft. from its roots, at a time, too, when the sap is dormant and there will not be any danger of bleeding (loss of sap) when the latter rises naturally in the young rod.

But circumstances may occur which would prevent the due pruning back of the young rod, or cane. All young Vines that are not pruned at the present time must not be cut in the usual way, but treated as shown in the sketch. It is a very simple matter. Directly the buds burst into growth, begin at the top and remove every one from that portion of the cane marked Nos. 1, 1 when the young shoots are half an inch long. Leave this denuded portion uncut till midsummer or the following autumn, then cut it off at the two dark cross lines No. 2. All young shoots below this point must be retained. The top

one, marked *a*, will be the leader, and the others, marked *a*, *a* also, must be trained to right and left respectively, the points being pinched off when they have grown 2ft. long.

These three shoots will lay the foundation of the new Vine. The other shoots, marked *b*, *b*, *b*, should be stopped when they are 1ft. long and be cut away entirely at the autumn pruning. If left to grow 1ft long the first year they help, considerably, to establish the young Vine.

The old spur often causes much anxiety to the beginner, as so many young shoots grow from it; also air-roots, in the case of old Vines

DISBUDDING NEWLY BROKEN VINES.

with defective root-action are subjected to too much atmospheric moisture. Only one young shoot must be retained—the one on the previous year's wood, and marked *e* on the sketch. All the others, marked *d*, *d*, and the air-roots marked *e*, *e*, must be rubbed off.

The spur shown is one year old; it has been pruned back to two eyes, or buds, *f* and *g* respectively. The one marked *f* is the one to retain.

Many old Vines, especially those that have been neglected for a number of years, very frequently bear numbers of young shoots, shown at *h*, *h*, *h*, *h*. These shoots must be removed while quite small, unless any of them would prove useful to form a new spur in the case of gaps on the old rod.

GEORGE GARNER.

ECONOMY IN THE GARDEN

A Space-saving Idea for Frames and Greenhouses

PRICKING-OFF time has arrived or is coming for numbers of seedlings which, unless promptly attended to, will spoil one another in boxes. Tomatoes and summer bedding plants of many kinds require to be pricked into boxes or thumb pots if they are to make good specimens. The poor harassed gardener who is limited with his frame and greenhouse accommodation often scratches his head (I do not know why this is conducive to thought, but it often helps) and wonders "where he is going to put all them danged" (but he expresses it more forcibly than this if his employer is out of hearing) "boxes and thumbs."

It is always an education to see how a professional gardener works, and I never lose a chance of watching one. Priding myself on the production of sturdy, short-jointed Tomato plants, obtained by early pricking off and inserting the seedling in the "thumbs" right up to the seed leaf, I was only too glad to see a "real gardener" carry through this operation a short while ago.

Like myself, he had a crowded greenhouse at the time when his employer ordered him to supply some few hundred Tomato plants. I should myself have looked round the house and have wondered where I was going to "put the danged things," and should probably have decided to box them off for a start, potting them up later on. But what do you think the gardener did with them? He put them into thumb pots, but there were two seedlings in a pot, and each seedling was placed as close to the pot's edge as possible!

As this was the first time that I had seen seedlings so pricked off, I asked the why and wherefore of the operation. The first reason for this was that space was limited and one hundred seedlings could be grown on in fifty pots until they were sufficiently large to be transferred into larger ones. When this became necessary, the potful could be easily divided into two portions, each containing the majority of roots of the respective seedlings. The gardener maintained that in this way less check resulted than if they had been boxed.

The reason for placing them close to the edge of the pot was to encourage quick rooting. Everyone knows how much quicker cuttings will root at the side of a pot than when inserted in the middle. It is the same when pricking off seedlings. The warmth of the frame or house immediately induces new root action, with the result that practically no check is felt and the seedlings rapidly get away. Saving of time is thus effected.

The gardener said that he would prick off his seedlings in exactly the same manner even if he had sufficient space to allow of his doing so in single pots, *i.e.*, he would put one seedling in each pot, but would plant it at the edge of the pot and not centrally, as nine out of ten amateurs would do it.—C. P.

Waste-saving Trench Gardening

TRENCH gardening as usually conducted is not only extravagant, but wasteful. Travelling up and down the country viewing gardens as I do, I often see trenches with single rows of plants in them, and sides sloping at an angle of almost 45°, instead of being vertical as they should be. What waste of ground! of manure! and of water!

Certainly with costs at what they are, every effort should be made to make the culture of crops in trenches as economical a matter as possible. This can be done if one is willing to expend a trifle longer in digging the trenches and at the same time is not above doing a little rough carpentry.

It is most important to make the trenches amply wide and to dig them early. It may sound ridiculous to urge the digging of Celery and Leek trenches in March, but it is by no means too soon for the work to be done if the soil on each side of them is to settle properly. Such consolidation is absolutely necessary if the trench ridges are to be cropped up to the edges.

Twelve inches to 15ins. should be the minimum width for all trenches. It should then be possible to get three rows of such plants of Celery and Leeks in each trench, not, of course, putting the three plants opposite one another, but placing them quincunx fashion, so that each one stands opposite to a space between two others.

The sides of the trench should be cut as near to the vertical as possible, and an effort made to hold them up.

There are several ways of supporting trenches, one of the best being to let in old boards at each side of the trench, putting them on their edge and in a vertical position. Behind them soil can be filled in. The boards should be made fast at each end and half way down the trench by driving in some short, but thick, garden stakes.

Even where there is an abundance of old wood, the above seems rather wasteful, so that an adaptation of it may well be carried out in gardens. A piece of board about 4ins. wide all along should have much longer legs nailed on to it at intervals. These should then be driven into the trench each side, and the whole board pushed in until its edge is just level with the surface of the ridge. After all, it is the top part of the ridge which falls in; the under-soil is usually much too solid, and thus if the top is held up by the board on legs the bottom will be all right.

The increased area which is thus made available for cropping is surprising, and the increased amount of food got from the land well repays the little extra trouble occasioned.

Now, as to economy in the matter of manuring the trenches. I consider it advisable to manure them *gradually*. Celery and Leeks should not be planted out yet awhile, so that the trenches may be left open. There may be thrown into them, as collected, all the spare weeds, turf verges, old cabbage leaves and general "trimmings-up" that become available. As each section of trench is filled with this material to the depth of about 6ins. or 8ins., soil should be thrown over it. It will then rot down and turn into manure by planting-out time. Where this is done the rubbish heap will occupy only a quarter of the usual space, as all suitable rubbish will go into these trenches.

Water is scarce in some districts, and in any case its cartage is expensive. Trenches, as usually formed, allow a big lot of water, and of liquid manure also, to soak into the sides instead of going down to the roots of the plants. Naturally, if boarding is sunk well down, it will obviate such waste; but it is not recommendable to do this, as the wood, however well painted or soaked in preservatives, is apt to decay, and decayed wood harbours fungi and is bad for the soil.

I have found it advisable, instead, to take out a little channel on each side of the trench, close to the side, about 2ins. deep. Into this is put the very thinnest line of concrete that one can

manage, using well crushed stone for making it, and not coarse gravel, and then follow this up for about zins. or zins. with a thin lining of cement and sand right along the sides of the trench.

When all is dry the soil can be replaced; then if the trench is partially flooded, one will find that the water does not soak into the sides, but goes straight down into the soil and is available for the roots of the plants. This method is not expensive, as it might at first sight appear, for one lining should last two or three years, if not longer, and need in no way interfere with the manuring of the trench. The spent humus is, of course, dug out after the plants are lifted and

fresh material thrown in. Trenches so treated can remain open for several years, though, of course, the upper boarding should be removed and well scrubbed, to remove earthworms, etc., and thoroughly soaked in preservatives before being replaced.

There is another way of gardening in trenches economically which is sometimes favoured. In this case no flooding of the trenches is attempted. Small zin. drain pipes are inserted vertically between the plants at intervals of a few feet of trench, and water or liquid manure is poured down these whenever it is required. This, however, is not as satisfactory as the other way and wastes ground in the trench. YORKSHIRE.

SOME OUTSTANDING NOVELTIES AT VINCENT SQUARE

THE most recent R.H.S. Show was particularly noteworthy in two respects and both connected with Orchids. Lieutenant-Colonel Sir George Holford set up a record by having eight awards (first-class certificates and awards of merit) for new Orchids of the same genus, and a new generic name was coined for a multi-generic hybrid, so *Potinaria* is recorded for the first time. If the Orchid Committee had followed the usual custom in such things this most brilliant Orchid would probably have been christened *Sophro-lælio-cattleya-Brasso-cattleya Juliettae*, but, even to the Orchid enthusiasts who delight in many-barrelled names and accept such as *Sophro-lælio-cattleya*, this would be too cumbersome. So a pretty compliment was paid to an eminent French Orchidist, and the glorious flower has a handy name.

The collection of *Cymbidiums* by Sir George Holford was stupendous and contained a great number of lovely plants, of which the best were those selected for award. The general exhibit received a gold medal and a silver-gilt Lindley medal. It is an understood thing that the gold

medal is for the owner of the collection, while the Lindley medal for cultivation becomes the property of the grower. For the most part these graceful, long-lasting Orchid hybrids have sprung from *Cymbidium giganteum*, which was introduced from North India in 1837, and *C. eburneum*, from the West Indies in 1846.

Chief among the general floral exhibits were hardy flowering shrubs which had been gently forced into bloom and so had retained all their natural beauty with the added charm of a certain delicacy of colouring. These included excellent *Wistarias*, *Prunus triloba*, several varieties of *Pyrus Malus*, such as *floribunda*, *purpurea* and *spectabilis*, and a most graceful little *Cytisus*—*White Gem*. At this season such shrubs may be gently hastened into bloom with the expenditure of very little fire-heat, and they brighten the home and conservatory for quite a considerable time. The earliest of the Himalayan *Rhododendrons*, of the type that flourishes so well in the Cornish Riviera and in favoured spots elsewhere, were to be seen, and, no doubt, these will soon be followed by more generous quantities from the Falmouth district

Spring bulbs were fairly represented by *Hyacinths*, *Tulips*, *Narcissi* and such, growing in bowls of fibre. Of these the *Tulips* by Messrs. Sutton and Sons made a highly decorative display, while in another place the same firm had a secondary show of *Crocuses*. These were also very well grown, and presumably the exhibit was designed to show the value of a white and shades of purple colour scheme, and in this it was most successful. Besides *Hyacinths* and *Narcissi*, Messrs. Bath and Co. had some most desirable little bowls of growing *Snake's Head Fritillaries*. These charming flowers do not seem to be in such favour as their many merits warrant.

Violets are always welcome, and the bunches by Messrs. Maxwell and Beale were not only of unusually large blooms, but were deliciously fragrant—in marked contrast to the enormous quantities that are now on sale in the streets, which have all lost their perfume. The bunches of *La France*, grown under glass, were naturally the better of the two sorts; but *Princess of Wales*, gathered from the open ground, were of more than usual merit.

A dozen dishes of an Apple named *Souring*, shown by Captain H. B. Tate, Billesley Manor, Alcester, were of excellent appearance. These and the new seedling were the only home-grown fruits on view, but there were samples of South African *Plums*, *Peaches* and *Pears* of beautiful colouring.

The Fruit Committee "sat on" some branches from an Apple tree supposed to be suffering from attacks of American blight, but were seen to be from that old variety *Burr-Knob*, or one very like it. This is an October to November culinary variety which produces a "profusion of burrs on the branches which emit incipient roots. If a branch furnished with these burrs is inserted in the ground it will take root and become a tree." It is also known as "Bide's Walking-Stick," a name which "originated from a person of that name having cut a branch for a walking-stick in Cheshire and brought it to his place near Hertford, where, having inserted it in the ground, it took root and became a tree." ("Hogg's Fruit Manual.")

NEW AND RARE PLANTS.

***Potinaria Juliettae*.**—This is a new Orchid with an entirely new name. It is the result of a cross between *Sophro-lælio-cattleya Marathon* and *Brasso-cattleya Ena*, so a new genus became necessary, and one was formed in compliment to M. Potin, the President of the National Horticultural Society of France, who has long been an authority on Orchids. It is a most glorious flower of sparkling vivid colouring that seems, as it is, full of life. In form it may be likened to a flattish *Cattleya* of medium to large size. The sepals are brick-red, with definite blood-red lines. The corolla is rosy carmine, and the broad lip is intense crimson, shading to orange-crimson at the base. First-class certificate to Messrs. Charlesworth and Co.

***Cymbidium Bronze Beauty*.**—A large arched spike, bearing many flowers. The green sepals and petals are freely stippled with bright brown, giving a bronzy appearance. The lip has a crimson blotch and lines. First-class certificate to Lieutenant-Colonel Sir George Holford.

***Angulocaste Sanderæ*.**—A beautiful hybrid Orchid, which in general appearance favours its *Lycaste* parent. A vigorous plant was shown, bearing plenty of almost golden yellow flowers. The outer petals are of soft yellow colour, while the centre is deeper in tone. First-class certificate to Messrs. Sander and Sons.

***Cattleya Tityus Wedding Bells*.**—A handsome flower of large size and perfect form. The rich

THE GRACIOUS CYMBIDIUM MIRANDA VAR. BRONZE BEAUTY.

velvety lip is of crimson lake colour and has golden and brown lines in the throat. The sepals and petals are a pale purple. First-class certificate to Messrs. Sander and Sons.

Cymbidium Thrush.—A stout, arched spike densely set with blooms. The sepals and petals are of greenish ivory colour, flushed on the outside with brownish purple. The lip is lightly spotted with crimson. First-class certificate to Sir George Holford.

Cymbidium Redstart.—An erect spike of roundish flowers. The hooded segments are lightly flushed with purple, while the lip is freely spotted with carmine, and the golden crest is very pronounced. Award of merit to Sir George Holford.

Cymbidium Redstart var. Brighteyes.—The great charm of this variety is the pale blush segments and chocolate-maroon spots on the lip. Award of merit to Sir George Holford.

Cymbidium Curlew var. Rosy Gem.—This was the most uncommon of all the Cymbidiums at the Show. The rosy pink to crimson markings on the lip rose clear above the old ivory coloured segments. It is a relatively small plant, but it bears a compact arched spike. Award of merit to Sir George Holford.

Cymbidium Kittiwake.—The milk-white segments surround a crimson lake spotted lip, which contains a golden crest—quite a startlingly beautiful combination. Award of merit to Sir George Holford.

Cymbidium Butterfly.—A large slightly arched spike, bearing many blooms of old ivory coloured segments and crimson-bronze lip. Award of merit to Sir George Holford.

Cymbidium Mirande.—An almost weirdly beautiful flower. The greenish-yellow sepals surround an ivory-white lip spotted and blotched with dull carmine. It is a graceful spike, evenly furnished with flowers. Award of merit to Sir George Holford.

Brasso-Lælio-Cattleya Camada.—A deliciously scented golden-citron-coloured Orchid which has a large, admirably fringed lip. One of the most beautiful of the many beautiful Orchids at the Show. Award of merit to Messrs. Charlesworth and Co.

Odontioda Venus.—A long, graceful spike of relatively large, roundish flowers of pale lilac colour, heavily marked with dull crimson. Award of merit to Messrs. Armstrong and Brown.

Odontioda Cissie.—Another graceful variety with blush lilac ground colour. The markings are of deep maroon, and the golden crest is very prominent. Award of merit to Messrs. A. and J. McBean.

Odontioda Latona Lilacina.—This is a very robust spike, bearing numerous roundish flowers with dull chocolate markings. The lilac lip sets off the golden crest. Award of merit to Messrs. Stuart Low and Co.

Sophro-Lælio-Cattleya Mars.—A very handsome flower. The light purple segments have a darker centre, and the slightly incurved lip is of velvety crimson colour. Award of merit to Messrs. Armstrong and Brown.

Saxifraga Brookside.—This novelty is stated to be a cross between *S. Burseria* Gloria and *S. Pauline*. It favours the former, but is inferior to it in merit. The flowers are rather smaller and not so pure a white. Shown by Messrs. R. Tucker and Sons.

Primula Juliae \times **Wilson's Blue.**—Several plants of this cross were submitted to the Committee, but evidently did not impress them, as no award was given. The flowers and forms are rather variable, but mostly of *P. Juliae* type. One named Lord Lascelles had a few flowers of reddish maroon colour. Profusion bore most flowers, but they did not show any advance on

other sorts. Purple King had the largest flowers, and this was nearest the ordinary garden Primrose in habit. Shown by Messrs. R. Tucker and Sons.

Anchusa myosotidiflora.—Although not a new plant, this pretty plant, bearing plenty of forget-me-not blue flowers, was evidently rare to many visitors, who greatly admired it. There were many pots of well flowered plants about a foot high. It was introduced from Siberia in 1825 and will thrive in a sunny place in ordinary soil. Shown by Mrs. H. J. Tennant.

Narcissus Princess Victoria.—An incomparable variety with a very long stalk and good

yellow flowers with widely expanded orange-tipped cups. The perianth segments are curiously curled at the edges. Shown by Mr. W. A. Watts.

NEW FRUIT.

Apple Pope's Nonsuch.—This seedling dessert Apple was considered by the Committee to be somewhat similar to Radford Beauty, a Nottinghamshire variety. It is a roundish fruit, yellow skinned, heavily flushed with red on the sunny side, of good flavour and is a good keeper. Shown by Mr. W. Pope, Welford Gardens, Newbury.

QUEENS' GARDENS

Being a description of the gardens in the Annexe at the Ideal Home Exhibition now proceeding.

THE display in the Floral Annexe to the Ideal Home Exhibition, the proceeds of admission to which go to the Middlesex Hospital, is, for the season of the year, wonderfully fine. Messrs. James Carter and Co. are responsible for a garden modelled to half size from H.M. Queen Alexandra's favourite garden at Sandringham. This is an epitome of the English spirit of gardening—quiet, restful, restrained and wonderfully finished off. It was much admired by H.M. Queen Alexandra, who visited the Exhibition on the opening day. The foreground is laid out in parterres of scroll design introducing red, pink and mauve (William Copland) Tulips carpeted with *Erica carnea*, while, around a handsome central well-head, Emperor Daffodils are massed. Connected pillars frame a less formal background planted with various conifers and relieved with a variety of Narcissi in informal but balanced array. The entrances to the garden are defined by miniature ball-capped pillars. Two larger ones alight with masses of the pink *Prunus triloba* fl.-pl. complete a very charming and satisfying arrangement.

The Princess Alice, Countess of Athlone, who opened the Exhibition on Wednesday, 1st inst., is responsible for the design of the garden carried out by Messrs. Gaze of Kingston-on-Thames. Arranged on two levels—both very considerably above the floor of the Annexe—many hundreds of tons of soil were necessary for its construction. There is but one entrance to this exhibit, but the exterior, which displays a Yew hedge surmounting a coursed-random garden wall, provides a welcome relief to the eyes after an inspection of the general effect. The Yew hedge, referred to, is singularly well carried out. It is not easy to produce a credible Yew hedge at an Exhibition, but Messrs. Gaze have done it. A large portion of this hedging is 8ft. high. One enters the garden up a flight of steps under lintels spanning two pairs of simple but elegant pillars and an arch of Yew. At top of the steps is a little paved garden with an oblong Lily pond with semicircular ends. The borders which surround it are filled with Forget-me-nots, blue Hyacinths, Murillo and William Copland Tulips, standard pink Indian Azaleas, Wistarias, blue Hydrangeas and *Prunus triloba*. A further flight of steps gives access to a turf path ending in a seat. On either hand are borders filled with plants similar to those already mentioned.

A blue garden designed by the Queen of the Belgians is carried out by Luff and Sons of Wimbledon Park. Enclosed by low York stone walls, this garden has for its central feature a square Lily tank and fountain. The surrounding banks are thickly carpeted with *Scilla sibirica*. Beyond these, again, blue Hyacinths are arranged which

do not altogether assort as to colour with the Scillas. Large quantities of other blue-flowered plants, notably *Cinerarias* and Forget-me-nots, are employed, until the total effect is a little overpowering. Separated from this exhibit [by one of the public ways, Messrs. Luff have a smaller exhibit which attracts by its fragrance. Here, massed on either side a fine wrought iron gateway, are banks of Magnolias, including the beautiful *M. stellata*, *Skinnias*, Azaleas and *Mezereons*, while a picturesque thatched garden-house serves as an office.

A Dutch firm, Messrs. C. B. van Nes and Sons of Boskoop, display, in the garden designed by H.M. the Queen of the Netherlands, masses of Lilacs, *Rhododendrons* and Azaleas belonging to the mollis and Ghent sections. Despite the well kept Box-edged gravel paths and the very beautiful vase which forms the central feature, one feels this exhibit to be massed banks of flowers rather than a garden. Probably Messrs. van Nes had not sufficiently appreciated that model gardens in such a setting must carry their own repose. Here is no helpful solid background of shrubs and trees such as in the countryside might justify such massed colour.

For H.M. the Queen of Norway, Messrs. R. Neal and Sons of Sevenoaks have fashioned a sunk garden, planted with pink and blue Hyacinths, Emperor Daffodils and Indian Azaleas of that deep rose shade which holds more than a hint of magenta. Here, again, the colour is a little overpowering.

Mr. Ernest Dixon of Putney has effectively carried out the idea of H.M. the Queen of Rumania. This is a restful little garden and the purple and orange shades which distinguish it are not overdone. Alas! close inspection reveals that most of the flowers are artificial. The principal feature of this garden is a sunken square, its retaining walls capped with purple *Aubrietia* and its swastika-shaped central bed filled with orange Wallflowers. Small Orange trees in vases complete the effect.

Messrs. Whitelegg and Co. of Chislehurst have, in addition to the garden designed by H.M. the Queen of Spain, a triangular rockery arranged on staging which displays many kinds of *Kabschia Saxifrages*, hardy *Cyclamens* and *Lenten Roses*. Their more important exhibit, said to be modelled on a garden in Seville, comprises a seat-surrounded fountain of typical Spanish design with Box-edged beds filled with Indian Azaleas, *Epacrids* and Palms. The effect is quaint and pleasing, though the central seats, as was, perhaps, to be expected in so small a garden, dwarf to some extent the rest of the exhibit.

Perhaps by contrast with the riot of colour elsewhere, Messrs. J. Waterer, Sons and Crisp's garden seems rather "flat, stale and unprofitable."

The yellow, which is its essential colour, is largely contributed by *Cupressus filifera aurea*. Golden shrubs are not exactly ideal for formal garden effects, especially those of an essentially informal habit of growth. The colouring was, no doubt, part of Lady Patricia Ramsay's design, but one could not help feeling how much more effective and how altogether charming this garden might be if relieved by more cheerful colour. A tiny circular lawn and a square pool with the corners taken off to make it eight-sided are pleasing features.

Messrs. R. Wallace and Co. of Tunbridge Wells have five miniature gardens on view. Four of these represent the gardening ideals of four children of our Royal Houses. Two are neat little formal gardens, but the space at disposal gives small scope for individuality or distinction. The other two are, respectively, miniature rock and wild gardens, both admirably carried out. The groups of Birches with admirably arranged colonies of Daffodils, etc., form a beautiful picture and display to advantage the art which conceals art. The contouring of the ground could not well be improved upon. The little rock garden is, in its way, equally good. It would be difficult to stage one more effective in the space at disposal. In another quarter Messrs. Wallace have yet another small garden, this time an Azalea garden aglow with all the pure and wonderful colouring obtainable in the mollis hybrids.

The garden designed by H.R.H. the Princess Mary is a rock garden carried out in a grand manner by Messrs. Pulham and Sons. It is staged against an effective back-cloth which enlarges the apparent size of an exhibit extending to 1,800 square feet. Large as is the exhibit, it is hardly large enough for the huge waterfall the firm have contrived, nor do the rocks bordering the fall look weighty enough for the margin of such a flood. No attempt has been made to set up a May garden at this season. The firm are to be congratulated on resisting the temptation to rely too largely on colour to produce effect.

Messrs. Allwoods display a border of perpetual-flowering Carnations; Messrs. William Duncan, Tucker and Sons show a model greenhouse with growing plants *in situ*; and Mr. H. D. Thompson of Adam Street, Adelphi, has a miniature hard green tennis court in his special (provisionally protected) material, combined with an exhibit which demonstrates the beauty attainable by the use of steps and paving. An exhibit by Messrs. Gilliam and Co. shows the value for garden-houses, walling and paving of the Somersetshire stone from the Bryscom Quarries. Messrs. T. Crowther and Son of Fulham have a fairly representative collection of garden statuary; Messrs. James Carter and Co. have a large collection of garden seeds and tools, as have Messrs. A. W. Gamage and Co.

A new and noteworthy exhibit is that of the J. P. Super-Lawnmowers, Limited, of Leicester. The machines, which are at present only in production in the 12in. size, are not inexpensive, but, mounted on ball bearings and driven by dust-free, sun-and-planet gears, and adjusted instantaneously without a spanner, they have every appearance of a workmanlike job and should prove a good proposition.

Also new, though this is by no means their "first time out," the Fibrex pervious flowerpots, shown by Messrs. Harvey, are sure to claim their share of attention.

Apart from the horticultural exhibits in the annexe, a few garden sundries are to be found in the main exhibition. Among these one noted the Slade movable frames and a display of Rito, the well known Molassine fertiliser. "Windolite," one of the most recent substitutes for glass in frames and sheds, is also on show.

In connexion with the Ideal Homes Exhibition the *Daily Mail* has thrown open, at Welwyn Garden City, a number of newly-erected houses embodying economical ideas both for construction

and upkeep. There is, however, little there at present to interest the garden lover, and the gardens provided are, truth to tell, far too small, especially considering the distance from town.

LENTEN ROSES

These quaint and charming flowers are ideal for the shady fernery or the Bamboo dell in a soil abundantly supplied with humus.

INSTEAD of bemoaning the fact that we have a cool shaded border facing north, on which the sun never shines, we should welcome it as a happy home for the lovely Lenten Roses, for these, with the addition of a few of the choicer hardy Ferns with their graceful lacy arched fronds for summer, provide attraction and beauty through the whole year. When the rest of the garden is bare and leafless

with purplish crimson and H.g. sub-punctatus, white, faintly spotted at the base of each petal. For flowering from February to April there is a host of varieties, many of which are rather similar, but the following will be found a desirable collection: H. Benary, white, heavily spotted with crimson on the inside; Dr. Moore, rose pink, with long stems; Duchess of Cleveland, lilac rose; Mont Blanc, very fine, pure white; punctatissimus,

QUAINTLY BEAUTIFUL. THE LENTEN ROSE HELLEBORUS ORIENTALIS.

and the fern fronds have turned sere and brown, the Christmas Rose steps forward and—despite the cold and short days—expands its pure white flowers. The type is one foot tall with large leathery foliage, but even finer and earlier than this is *Helleborus niger maximus*, which commences to flower in November and continues well into January. This is more vigorous than the type and reaches half a foot taller, while the flowers, though white inside, on the exterior are rosy purple. We are concerned to-day, however, with the later flowering orientalis varieties, and I merely mentioned the above as a means of extending the season over which we may cut lovely flowers, quite unprotected in the open air. The beautiful foliage is quite distinctive, while they embrace quite a wide range of colour. For flowering in January and February the following varieties should be chosen: H. abschasicus, with large deep crimson purple flowers; H. guttatus, white flowers spotted

rich purple, spotted inside with deeper coloured spots; and sub-junctatus, white. The species viridis, bright green, and its variety, purpurascens, dove grey, also flower at this season.

The culture is very simple; the less the roots are interfered with the better. Planting is best done in early spring and they have a strong preference for a rich turfy loam, so that it pays to make up a small border, a couple of feet deep, with this. Take care that they never want water, especially when planted close under a north wall, for, often enough, quite heavy rain does not touch the soil at all in such a position as this. Subsequent culture in following years consists in affording a good dressing, 3ins. thick, of old manure each spring, as soon as the flowers fade.

This is when the new roots are emitted and the top dressing serves the double purpose of feeding the roots and keeping them cool and moist through the summer.

H. W. CANNING-WRIGHT.

CORRESPONDENCE

A CURIOUS PLANT.

THE enclosed photograph may be of interest to your readers. It represents the rootstock of *Testudinaria elephantipes*. One can take one's choice between this name and the more readily spoken Elephant's Foot, Hottentot Bread or Tortoise Plant, as it is variously called. Though far from a readily procured plant, I have come across one or two good examples of this freakish thing in this country, and once had the good fortune to see a small batch of plants during the process of raising from seed. This is not at all a difficult matter once the seeds are obtained, and the best way to attempt it seems to be by making enquiries from friends in South Africa. Germination is fairly rapid in a temperature of 60° to 70°. They should not be interfered with while quite small. The twining stem should run to about 6ins. or 8ins. first before potting them off singly in small pots, using a compost of sandy loam and leaf-mould. Treatment as to watering, &c., is pretty much the same as for the Cacti, and the plants gradually increase in size from year to year until they produce a huge, woody tuberous rootstock marked like the shell of a tortoise. From the apex of this rises slender branching stems that—in strong specimens—attain a height of between 30ft. and 40ft., with heart-shaped leaves and small, bell-like greenish yellow flowers.—CROYDONIA.

A NOVEL POT PLANT.

THE fibrous section of *Begonia* is mostly associated with bedding out, I believe; but during the last two months I have proved their truly great worth as dwelling-house plants—and this discovery was made almost accidentally. Pricked out, but unwanted, seedlings of last spring's sowing were left in box and pan in a cold frame until, as nearly as I can remember, some time in October, by which time the foliage had taken on a lovely reddish hue, and the plants, obviously somewhat stunted, were doing their best to make a show of flowers. Instead of discarding them, as was threatened more than once, I took out a ball of several plants together and placed these in 4½in. and 6in. pots, in which the plants gradually improved in growth and flower until in December I tried them for house decoration. Two clumps in particular gave exceptional pleasure, as they were in the drawing-room in the same vases for quite six weeks, the position being a large window where good light was available, and this at midwinter—C. T., *Amphill*

THE EUCALYPTI.

A PROPOS of the note on page 46 of THE GARDEN by Walter Smyth, I thought the extract from a letter I received from Mr. G. Flemwell, the author of several books on alpine flowers, would be of interest at this present inclement season.

"... And now let me tell you of a Switzerland equally interesting and wonderful and beautiful, though not considered typical. I left Zermatt frost-bound and in snow; I left Brigue, mist and wind-ridden; Lucerne was enveloped in thick fog and rain; but directly the St. Gothard

apple-like fruit. And they are skating at Lausanne and at Arveyes! . . ."

I wonder if it is possible, with protection, in some of our sheltered valleys in the warmer parts of Cheshire to grow the Eucalypti, Camellias and Mimosa?—J. P.

PRUNING FRUIT TREES.

I HAVE read with great interest the articles on "Fruit Trees," and cannot but help agreeing with Mr. McCowan that had Mr. Pearson given a list of those kinds which, grown as pyramids, gave the best results, and Mr. Thomas done the same with those which, in his opinion, did best as bush trees, and the best distance to plant apart, their contributions would, indeed, have been of greater help.—W. MASON, *Wisbech*.

"PREPARED" DUTCH HYACINTHS.

IN writing of these "Prepared" Hyacinths I must say at the start that I am writing only of white Miniatures, which were obtained last year to take the place of Roman Hyacinths, which were so dreadfully dear that my firm—along with many others—thought it best to let these French bulbs severely alone until the growers were a little more reasonable in their prices.

These special Hyacinths are, as many of your readers are no doubt aware, first, small bulbs of two or three years' growth; secondly, they are lifted while still green, and are then stored in heated rooms for a certain time, which gives them an artificial ripening. This preparation enables one to force them into bloom with good results some ten days earlier than is possible with unprepared bulbs. Last season my firm had a number of these prepared Miniatures left, and to cut loss as far as possible they were planted in a greenhouse to produce cut blooms for the market. They were planted in November and were kept right through their growing time at about 50°, falling sometimes at night to very near the freezing point. The resulting crop has been really wonderful. The first blooms were cut January 31—quick work from bulbs planted as late as November—and the whole lot were cleared by mid-February. The spikes have been very good for such small bulbs; in fact, some have been nearly as large as those produced by first-sized bulbs, while out of some two thousand bulbs just *one* failed to flower! The whole crop has made very healthy and regular growth, and the flower stalks have been quite long enough for cutting, for which the smaller spikes are quite suitable. The scent is not at all overpowering; in fact, not very different from that of the Roman Hyacinth. The name of the variety is L'Innocence. It seems really surprising that people are still willing to pay about sixpence per bulb for Romans, while these prepared white Dutch Miniatures can be had for half that amount! To my thinking they are worth twice as much as the Romans, and they may, by early planting, be had in bloom by Christmas.

I have learned something by this little venture about the flowering of Hyacinths. It has always been thought necessary to place Hyacinths, after potting or boxing, out of doors under plunging material for many weeks before placing them in heat. Now with this surplus lot of bulbs we came to the conclusion that, first, the crop would not pay for much labour; secondly, that the bloom must be cut early to demand a ready sale. So we decided to bed them on a bench in the greenhouse without any preliminary outside or cold frame treatment, and the results could not have been better. A few pots of the very same Hyacinths were potted on August 18 and

THE REMARKABLE ROOTSTOCK OF TESTUDINARIA ELEPHANTIPES.

was passed, sunshine began to appear, and by the time Locarno was reached I was in summer heat and sunlight. Yet Locarno (thoroughly Swiss, though, of course, Italian-speaking) is only just on the southern side of those Alps where the Rhone Glacier nestles! and we are surrounded by those Alps' foot-hills! As the crow flies it is 'no distance'; yet in the garden of this Villa Miralto and at this present moment (December 14) there is an Orange tree bearing over a hundred Oranges, and by its side is a great Eucalyptus in full bloom and a Lemon tree carrying ripening fruit! Palm trees are everywhere (mostly *Chamaerops excelsa*, which is a weed here, seeding itself all over the place). Camellias are just coming into flower (we shall have a bloom or two for Christmas); the Mimosa is blooming; and the Japanese 'Kaki' trees still bear their orange

were placed in plunging material in a cold frame until the roots were at the bottom of the pot; they were then brought into the same house as the planted out bulbs, and they flowered about a week later than these, and were in no respect better. This seems to prove that the Hyacinth may be grown right along in a moderate greenhouse temperature without any cool treatment at all. The same cannot be said of Tulips or Daffodils; at least, I can speak with certainty of Tulips, for some which were tried last year in exactly the same way as this season's Hyacinths were, to put it mildly, not a success. They produced flowers of a sort, but in spite of shading, the stalks were almost non-existent, and the flowers were quite a failure from the cut flower point of view.

Those amateurs who have not yet tried these "Prepared Miniature" or "Dutch Roman" Hyacinths should make a note to procure some this autumn, and do not forget to ask for L'Innocence, as that cannot be beaten for growth, purity or delicate scent.—J. DUNCAN PEARSON, *Lowdham, Notts.*

THE NIGHT-SCENTED STOCK.

THIS is one of the supreme joys of the summer garden. I can never forget being taken out of doors one evening after dinner, at Balls Park, to smell the Night-scented Stock. A long and wide, partly-made and partly-filled, border had been sown with it. It was by far the largest patch of it that I have ever come across, and the scent of it that evening was prodigious. It is very seldom that it is possible for it to be grown on such a grand scale, for during the day the Night-scented Stock is one of the most forlorn objects possible. It looks as if it was all over with it, and anyone coming across a patch for the first time might quite justifiably root it up as "done for." But when evening comes!

How one would like to know what rouses it up! It cannot be a dance, or a card party, or a dinner, or some swell function or other. These are certainly powerful human stimulants, but they cannot apply to the vegetable kingdom. What is it, then? No one knows. Let us not worry about it. It is our part to be truly thankful that such a plant exists and that it is so easily grown and the seed is so cheap—even in 1922—to buy that there is no reason why a patch of it should not be sown not only in the large and stately garden of Balls Park, but also in the tiniest cottage garden on the Balls Park estate. Writing entirely at random, let me suppose 95 per cent. of gardeners know it; nothing like 95 per cent. grow it. Until as many grow it as know it, I trust a little space will be found in the columns of THE GARDEN at the beginning of every year for someone to sing its praises and to urge everyone to spend a few coppers on the purchase of some seed. Its present price is about eighteenpence, or less in some lists, per ounce. It would be difficult to spend a sixpence that would diffuse more pleasure than sixpennyworth of Night-scented Stock seed. Most catalogues call it, as is strictly proper, *Matthiola bicornis*. I had once an amusing query addressed to me after I had done my best to sing its praises. I suppose the Latin name is a bit frightening and we jub at it as anyone might do if recommended to buy *Cheiranthus* or *Callistephus*. This person was, however, converted and decided to buy. "But where could *Matthiola bicornis* be bought?" the person wrote. "Do you think I could possibly buy it in Paris?" Why Paris, I wonder? Let me say there is no need to go to Paris, or even to Sutton's, Carter's, Dobbie's, or that refuge of the seekers after rarities, Thompson and Morgan's. It would be a poor seed shop in a local town which

could not supply it, if wanted. Sow some of it every fortnight between April 1 and July 1, inclusive, if you can. At any rate, begin in April and go on as long as seed and spaces last.—JOSEPH JACOB.

THE RECORD OF GREAT DISAPPOINTMENT.

LIKE many others, the writer acclaimed the advent of *Primula Forrestii* to our British gardens. It seemed to be what we had longed for—a robust, healthy, beautiful yellow species which we might attempt in our gardens with a reasonable amount of confidence in its well-doing, and with every prospect of it giving us much satisfaction and real joy. But we have all been disappointed in its behaviour in our gardens in the conditions, say, in which *Primula japonica* would be exceedingly happy, or even in the drier border. We had some justification for hoping that it would be easy and delightful to us when it flowered and that it would prove a good hardy perennial. Its abundant, bold, healthy-looking leaves gave every promise of a satisfactory plant, and the accounts we heard of the big masses it formed in its own land afforded us some trust that it would be happy in these islands. But we forgot or deliberately overlooked the accounts which told us of the conditions under which it thrived in that native land. We were told that it came from the limestone cliffs of Yunnan, where in the hot sunny parts it flourished, and, not lacking in temerity, we planted it in borders or on rockwork, rashly hoping for success, disregarding all the while our heavy rainfall and our cooler sunshine. So we deserved what we got—rank failure and the loss of our plants. Some wiser mortals planted in the face of a wall garden and had a little—a very little—more success, and the writer well recollects seeing a plant in bloom which had been in the same place in a dry retaining wall for about two years and was condescending to live and bloom. But one swallow does not make a summer, nor does one plant of *P. Forrestii*, deigning to survive for a couple of years in a particular place, justify us in concluding that it will do anywhere under the same conditions. The truth is that there is little chance of success with it in this country unless in a sun-scorched limestone cliff or wall, where, practically sheltered from the winter wet, it has some prospect of surviving. But for this failing, so far as our gardens are concerned, it would be a worthy plant with its bold crinkled leaves, its good scape and its heads of sweetly perfumed yellow flowers. Alas that one has to say it!—as a garden plant it has even to give way to a good yellow *Polyanthus*, or, more attractive still, to that lovely and robust species of *Primula* which has more recently reached our gardens—*Primula helodoxa*. We may still desire to conquer the foibles—if we may call them that—of *P. Forrestii*, but we had better far devote our energy and our space to cultivating *P. helodoxa*, one of the brightest gems of the Primrose race and a splendid, yellow-flowered, healthy, obliging plant.—S. ARNOTT.

ST. FIACRE.

I WILL freely confess that my library is very much wanting in books that relate to the saints, and that was why I raised the query as to who St. Fiacre was and what he did to merit canonization. Mr. Jacob very kindly answers part of the question and leaves part of it unanswered, so that I am still ignorant of what the French gardeners' patron saint did that warranted the Church in raising him, an apparently poor working gardener, to so venerable a place. The only book accessible to me on the subject of saints is "Butler's Lives," and evidently so little was thought of St. Fiacre by the compiler of that

standard work that his biography does not appear in it. Where else shall I go to avoid astonishing my dear old gardening friends by my ignorance? Being the possessor of a French calendar is a very superficial means of knowing anything about saints, but on this subject that completes my stock. It would be interesting and instructive to know why my enquiring mind should put the saint and the cab together. There does not seem to be any logical sequence, and the operation would not enlighten me as to the reason why the good man deserved the honour of canonization. Nor does the fact that it has been my fate many a time to have to drive in a Paris *fiacre* help me towards a solution. Now I am going to get one in! Mr. Jacob says "it would appear to be a pure chance that his (the saint's) name is connected with cabs." Nothing of the kind; there is no chance about it, but a very good reason for it. The hired vehicle, commonly called a "fiacre" in French, was so designated because when they were first started the booking office (*bureau de location*) where they could be ordered or bespoken for hire was situated at the *Hôtel St. Fiacre*. You see there was a hotel named after him. But I still want to know what he did to merit canonization.—C. HARMAN PAYNE.

"THE GARDEN" AS A BOOK OF REFERENCE.

A PLAN which is even simpler than that mentioned by "J.P." (Cheshire) in the issue of the 11th ult. is my solution of the difficulty of keeping all copies of THE GARDEN or of selecting pages for binding, with the complication of indexing, or losing time in hunting up articles wanted. With due apology for the scant courtesy shown to the numerous articles of interest and expert knowledge, my method has for some time been to cut out those columns, or pages, or notes which I am likely to wish to refer to in future, and slip them into an ordinary alphabetical file, under the most appropriate letter, for easy identification when required. (Some thought is necessary to decide on the best index letter of a subject.) It is surprising how evenly the strips are distributed over the file; but if one letter gets crowded one can sub-divide with loose sheets in that division. Each of us would probably find a different compartment to hold the place of honour in the file.—A. H. B., *Old Hill, Staffs.*

A LOVELY BASKET PLANT FOR THE CONSERVATORY.

THAT a deal of misconception exists to-day as to the actual needs of *Achimenes* is evident in the fact that most people still look upon them as plants fitted only for growing in a stove house, and this idea has been perpetuated for years; so much so, that in few greenhouses are they to be found. But beyond a little extra warmth in which to start the tubers, nothing more than the temperature of an ordinary greenhouse is required to grow these beautiful flowering plants; indeed, from June onwards no artificial heat need be applied. The present will be found a suitable time to start the tubers, and four or five should be planted in a pot made up of two parts loam to three parts leaf-mould and coarse silver sand. When 2ins. or 3ins. of growth have been made, the little plants can then be removed to separate pots or planted in and around a basket—once a favourite method—where they are seen to advantage. *Achimenes* delight in a moist atmosphere of about 55°, and, started under such conditions, they soon make progress. As greenhouse plants they are deserving of wider culture, and it is to be feared that prejudice has militated against them.—CLAREMONT.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Early Potatoes.—On a warm, sheltered border a start may now be made by planting a few rows of one of the recognised early varieties. The tubers will be nicely sprouted in readiness if they were cut up in boxes as advised. For this early crop 18ins. to 24ins. will be enough from row to row allowing the sets 10ins. or 12ins. from each other. It will prove beneficial to the crop if, after drawing out the drills in readiness for the Potatoes, a liberal amount of well decayed, flaky leaf-soil be strewn along them before dropping the sets into position.

Peas.—Where such can be arranged there is no doubt that early Peas are better if sown in boxes and then transplanted as soon as strong enough, provided soil and weather are favourable. Whether such is practised or not the present time is suitable for sowing outside to serve as a succession or to make a start if not yet done. Early staking of Peas is at all times essential, and this is especially true of early rows, for it helps to break the cold winds from the young plants.

Artichokes.—Tubers of the Jerusalem variety should be planted as soon as possible, allowing a space of about 2ft. between the rows. Should any portion of the previous season's planting be still in the ground, lift them and store in sand to be drawn upon as required. The Chinese variety *Stachys tuberifera* may also be planted now in rows about 15ins. apart. The small tubers of this variety can be quickly dealt with by using a dibbler for the planting.

Leeks.—A liberal open ground sowing should be made now to provide what will probably prove the main batch of plants. At least one if not two more small sowings could be made later. Plants from a late sowing come in most useful sometimes when the earlier-sown lot are apt to have seeding tendencies.

The Flower Garden.

The Rock Garden.—Select a fine day and when the soil is in good workable condition prick over the crevices between and around the plants. At the same time take steps, if necessary, to restrict the coarser-growing plants. Stocks of plants raised for adding to collection or for filling up vacancies may now be gradually removed to their permanent positions. Ofttimes an added interest may be given to the alpine quarter by the introduction of a few annuals, and a list of those suitable is frequently given in the general seed catalogues so often advertised in these pages.

Chrysanthemums.—An increase of these accommodating border plants may readily be arranged for now. Dibble the young shoots into pans of sandy soil and keep them fairly close in a temperature somewhere near 50°. When rooted the subsequent treatment will depend to some extent to what purpose they are allotted. Where they have eventually to succeed an earlier-flowering plant they must either be grown on in pots or planted out in a reserve plot until required, but where it is possible to place them at once in flowering quarters so much the better, as valuable time and labour are saved for other purposes.

Pampas Grass.—The old plants or clumps require an annual clean-over and trim-up, and this should be seen to now, making also any further plantings contemplated. A few well placed groups of this grass are a great feature during the autumn.

Kniphofia.—From now until the end of the month is a suitable time to give these a trim over, and also for the lifting, dividing and replanting of them. These handsome plants arrest attention almost anywhere, but particularly so when boldly grouped. The best results are obtained when they are planted in a cool yet well drained soil.

The Hardy Fruit Garden.

Fruit Borders.—The pruning and planting operations having been finished, all the borders and plantations should be forked over. This will make more easy the passage of rain, sun and air, and at the same time give a finished appearance to the above operations. It may be necessary, particularly on light soils, to follow this work up a little later with a top-dressing of well rotted manure broken up finely. In the case of newly planted trees a more strawy mulching is suitable, and will be found of immense help in maintaining the soil for the roots in an even

state of moisture as the days lengthen and the sun gains in power and drying effect.

Fruit Under Glass.

Vines in flower require a somewhat drier atmosphere, but it is not necessary or even beneficial suddenly to cut off all the atmospheric moisture. For free setters, like Hamboro's and Foster's, a night temperature of 60° is enough, allowing a rise of 10° to 15° during the daytime with a nice circulation of air. As an aid to setting give the Vine rods a sharp tap about 10.30 a.m. so that the caps may be removed and pollen liberated to do its work.

H. TURNER.

(Gardener to the Duke of Northumberland)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—Sow these in quantity for the principal crop. Although accommodating in its habits and thriving in most situations, the Broad Bean rewards generous cultivation by producing heavy crops of fine quality. Sow in double rows 3ft. apart, allowing about 8ins. between the seeds in the row. Long-pod varieties, such as Harrington Windsor, Monarch Long-pod and Austin's Evergreen are commendable sorts to sow at this time.

Onions.—Sow now in the open in rich, well drained ground. If possible, give a liberal surface dressing of wood-ash or burnt refuse. Where the soil is light make firm by treading, afterwards raking the surface until a fine tilth is obtained. Reliable varieties are Ailsa Craig, Cranston's Excelsior, James' Long-keeping and Blood Red. Sow in shallow drills 12ins. apart.

Early Short Horn Carrots.—Sow these in shallow drills 10ins. apart on a sunny border. Choose a day when the ground is thoroughly dry, so that it may be well broken up and thus ensure plump little roots of the highest quality.

Celery.—Make a first sowing of an early variety in boxes containing a rich fine soil. Germinate in a mild hotbed or warm pit and keep fairly moist.

Raising Herbs.—Where it is desirable to replenish or form a new herb border it is found advantageous in many cases to raise a number from seed. These often prove more vigorous than those raised from cuttings or small divisions. Perennial herbs should be sown now in boxes and placed in mild heat, so that well established plantations may result before the end of summer. Old favourites, such as Mint, Tarragon and Lemon Thyme are grown from division of the roots, and may be successfully propagated in this way during the latter part of March.

Potatoes.—Plant first early sorts immediately the ground is dry and mild weather prevails. Select a warm, sheltered spot for this crop. Scatter leaf-mould and any other light, warm material along the trenches when planting. This gives the roots a satisfactory start and lays the foundation of a profitable crop.

Tomatoes.—A sowing to provide plants for the main crop should now be made. Sow thinly in pans of light porous soil and germinate in a temperature of 60° or 65°. Transfer the seedlings into small pots immediately the second leaves are formed. Keep the young plants as near to the glass as possible so that short-jointed, stocky growth may be ensured. When watering use tepid water and guard against draughts, as young plants of the Tomato are readily blighted when subjected to any sudden change of temperature.

Fruit Under Glass.

Melons.—Raise another batch of plants in readiness for planting out on hotbeds next month, and also a suitable number for successional crops in pits. Keep young plants growing freely, never at any time allowing them to become starved or pot-bound during the early periods of growth.

Strawberries.—Advance further quantities from the frame to the forcing pit, taking care to see that the foliage is clear of vermin and the drainage of the pots is in thorough working order. Earlier batches in bearing should be stimulated by occasional waterings of liquid manure and soot-water varied at times with an approved fertiliser.

The Flower Garden.

Hyacinth candidans.—Plant bold groups of this in the shrubbery border. It may also with advantage be planted in large beds in conjunction with autumn-flowering Gladioli or Montibretias. With its drooping, bell-like flowers it also makes an effective companion to the stiff but otherwise brilliant Tritoma.

Gladioli.—Plant these in the open where they are to flower. On heavy land the addition of some leaf-mould and sand gives the bulbs a more generous start. Where the plants are wanted for summer bedding the bulbs should now be potted up and grown in a cool frame until required.

Dahlias.—Start the roots of these now in a warm pit so that a good supply of cuttings may be obtained. Should part of the bed in a Melon-house be available, it will suit admirably. Pack round the roots with old potting soil. Spray overhead occasionally and thus induce the tubers to break freely.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Daphne odora (syn. *D. indica*), in common with other fragrant plants, is a great favourite although by no means so popular as it deserves to be. This is due no doubt to the fact that it is by no means easy to keep in good health for any length of time when cultivated in pots. If planted out in a well drained border in a cool conservatory it usually grows freely and keeps healthy for a number of years. In Devon and Cornwall it is a favourite plant, and one frequently sees fine, large specimens outdoors planted against warm walls. As grown by the trade it is usually grafted on roots of *Daphne Mezereum*. It is considered a difficult plant to propagate by means of cuttings, but, personally, I have never experienced any difficulty in rooting short side shoots taken from healthy plants. Cuttings may be inserted now in pots of sandy peat, standing them in a close case in a cool house until they callus. If they are then placed in a case with slight bottom heat they soon produce roots. The potting compost should consist of half good medium loam and fibrous peat, with enough coarse sand to keep the whole porous. Do not overpot, and water carefully at all times, especially during the winter months.

Freesias are usually grown from corms potted up during August and September. It is not generally known that they may be raised from seed and flowered the same season. If seed is sown during this month the resulting plants should, if well grown, flower next November. Here I refer to *F. refracta alba* and *F. Leichlinii*. The flowering of the coloured varieties is more uncertain. The young seedlings do not readily recover from transplanting, so it is, therefore, best to sow them directly into their flowering pots, 48-sized pots being large enough, the seedlings afterwards being thinned out to the required number. Germination may be hastened by standing the pots in a house with a temperature of 55° to 60°. When the seedlings are well up they are best grown in a cool, low house and kept well up to the roof glass. As soon as they have well filled their pots with roots they should be fed with dilute liquid manure and soot water.

Sparmannia agriceana is an old inhabitant of gardens, being introduced during 1790, but to-day it is by no means commonly seen, which is rather surprising when one considers that it flowers more or less for several months during winter and spring. Apart from its beautiful, white flowers, which are so freely produced, this plant is interesting, as the stamens are irritable, gradually opening outwards when touched. It is easily propagated by means of cuttings, and grows quickly and soon makes a large specimen. Trained as a standard some 3ft. to 4ft. in height, it is very beautiful. After flowering the plants should be pruned hard back, and from the beginning of July until September should be stood outdoors in a sunny position. This ripens the wood and ensures free flowering. It is probably because this is not done that one hears frequent complaints that this fine plant does not flower freely. There is a double-flowered variety, but it is not so beautiful as the type.

Aloysia eltiadora (the lemon-scented Verbena).—This fragrant plant is a general favourite. It should be pruned back now and, as it starts into growth, repotted, or large specimens should have several inches of the surface soil removed and

replaced with a top-dressing of fresh compost. This plant grows with great freedom when planted out, and is excellent for a cold conservatory, as it is hardy over a great part of the country if planted at the bottom of a wall and given some slight protection. Many cultivators find this plant difficult to propagate because they try to do this during the autumn, whereas it roots in a few weeks from soft cuttings taken from plants grown indoors during the spring.

Begonias.—There are numerous species and varieties of greenhouse Begonias which between them keep the greenhouse gay, more or less, all the year round. *Begonia gracilis* is a very beautiful species, the tubers of which should be started now in slight warmth. This plant is also known as *B. Martiana*, and must not be confused with

a section of *B. semperflorens* to which Continental growers apply the name *gracilis*. Other beautiful tuberous-rooted species that should be more generally cultivated are *B. Davisii* and *B. Pearcei*, both of which played an important part in the present-day race of tuberous-rooted Begonias, all the yellow-flowered varieties coming from *B. Pearcei*, and these even now show traces of its beautiful foliage. *B. fulgens* and *B. Baumannii* are also beautiful species. *B. Evansiana* is a herbaceous species, almost hardy, and if started now is very useful for autumn decoration of the conservatory, as also is the old garden hybrid *B. weltoniensis*. *B. Dregei* and *B. Sutherlandii* if started now will flower throughout the summer and autumn. J. CURTIS.

Royal Botanic Gardens, Kew.

THE TURNIP GALL WEEVIL

Follows an account of a serious pest which attacks the Cabbage and its relatives. Preventives, as far as known to date, are indicated.

THE Turnip gall weevil (*Ceutorhynchus sulcicollis*) is a snout-beetle which, as its name indicates, causes galls on the roots and bulbs of Turnips, Swedes, Rape, various forms of Cabbage, Mustard and some cruciferous weeds, such as Charlock. Probably the most serious injury is caused in the case of Turnips and Swedes, the other cultivated *Brassicæ* suffering only occasionally, except when grown under garden conditions. Evidences of the presence of the pest are exceedingly common all over the country, some galled plants being found in most Swede and Turnip fields. John Curtis (*Farm Insects*, 1859) states that, except for the symmetry of the bulbs being affected, the plants are in no way injured by the presence of the insects. This may have been so in the cases which came under his notice, but the injury is often very

severe, particularly where young plants are attacked, for, as F. V. Theobald (*Rept. Econ. Zoology S. E. A. C., 1906-07*) points out, "It is not so much the deformed, galled, necessarily stunted growth of the Turnip or Swede that is, however, of such vital importance; it is the too frequent attack on young plants when all future growth is stopped by these maggots that makes the Turnip gall weevil of

heating or may send them into flower, while the development of such plants as Broccoli is often seriously checked.

LIFE HISTORY AND HABITS.—If a galled plant be examined galls varying from the size of a pea to the size of a hazel-nut may be seen; often they run into each other, with the result that mis-shapen masses are formed about the lower portion of the bulb, or turnip-like swellings may be found on the tap root or stalk of the Cabbage (Fig. 1).

The galls are found to contain whitish-yellow legless grubs (Fig. 2). A gall may be single chambered and contain one grub, or several chambered and contain usually from four to five grubs, the number of grubs present depending on the extent of the infestation. Sorauer (*Handbuch der Pflanzen Krankheiten*) states that there may be as many as ten to twenty-five together; in a specimen of galled Savoy, recently examined, twenty-nine grubs were located. The whitish grubs, measuring at maturity from 5mm. to 6mm. (say, 1.5in. to ¼in.) are found lying in a curved position in the little chambers they occupy. They are wrinkled into numerous folds and are segmented, being clothed sparsely with short hairs or bristles which facilitate movement. The head is proportionately small and very pale brown; it bears two strong pointed jaws with distinct dark brown tips.

These grubs can be found all through the winter until about February, when they eat their way out of the galls and, entering the soil, construct small earthen cocoons in which they pupate. The quiescent pupæ (Fig. 3) are at first whitish, and through the outer skin the outlines of the adult insect can be seen. Towards the end of the pupal period the colour becomes darker, the eyes being the first to be distinguished, followed by many of the limb joints, which can be distinctly seen. Finally the pupal coat splits and the perfect insect proceeds to extract itself from its folds, ultimately appearing above ground as a black and greyish weevil (Fig. 4). This adult insect is about 3mm. (¼in.) long and is black with scattered grey and whitish scales; the underside is lighter in colour. The head is prolonged into a snout or rostrum, which bears the elbowed headfeelers or antennæ. The thorax is rather coarsely punctured and has a central groove and two small lateral tubercles. Its legs are entirely black.

Shortly after emergence, mating takes place and egg-laying goes on from May onwards. Theobald (*op. cit.*) states that the adults appear very irregularly from spring to early summer, and that they feed in the flowers of various

cruciferous plants. The eggs are laid by the female in small holes bored into the tissue of the stem below the surface of the soil, one egg being deposited in each hole. From these eggs hatch out the minute grubs, the feeding of which sets up irritation, resulting in the formation of a gradually enlarging gall. In the centre of this gall the larva lives and feeds by boring shallow holes into the tissue in various directions. In summer-time the length of larval life may be about four weeks, but this period lengthens out as winter draws on.

So far, little has been done in connexion with the control of this pest. As far as natural control is concerned, birds are undoubtedly one of the most important factors in limiting it, for Curtis mentions that "partridges are very fond of the maggots, and that is undoubtedly one reason for the Turnips being so attractive to these birds; they are there under cover and run about in search of the galls to pick out the hidden maggots." Theobald, also, refers to rooks as "picking at the galls and taking the maggots." In an infestation

Fig. 2.—The larva, magnified five diameters.

Fig. 3.—The pupa (x 6). Fig. 4.—The imago of the Turnip gall weevil (x 6).

on Cabbage that recently came under the writer's notice, it was found that where the stumps were pulled and left exposed on the ground many of the galls were pecked open by blackbirds and thrushes.

Where Cabbage is attacked pulling and burning the stumps have been advocated. In practice the burning of Cabbage stumps is a most difficult proceeding, and exposure to birds would probably be found satisfactory and far easier. Where poultry could be run on the ground after the crop has been cut and the stumps pulled, it is likely that in foraging they would destroy a considerable percentage of the grubs. When planting out Cabbage, a mixture of soot and lime, or of soot, lime and ashes, has been found to give some relief by acting as a deterrent. The mixture should either be dibbled in with the plants or else scattered round the plants and pricked in lightly. Where a crop of roots is only slightly attacked feeding the bulbs to sheep or cattle will probably check the pest quite effectively. If the crop is badly attacked, feeding it off with sheep would be helpful in that some of the grubs would be eaten and others trampled in. If this is followed by deep cultivation it will make matters more secure, and by the time roots are grown there again, in the course of the rotation, the land would be comparatively free from the pest. Theobald mentions that a good dressing of soot over Turnips and Swedes, soon after germination, is often beneficial as a deterrent.

Since the weevil will form galls on various cruciferous weeds, it is important that cleanliness of culture be observed, for weedy headlands and waste ground generally form a source of infestation.

Judicious rotation of crops is another important factor, since, if crops liable to attack follow each other or occur in adjoining areas, there is a great probability of their being attacked. Thus with this, as with many other pests, the best means of control will be found to be judicious manuring, a good rotation, hygienic methods and the other factors which constitute clean husbandry.

HERBERT W. MILES, N.D.A., F.E.S.

Fig. 1.—Stem of an infested Savoy.

such importance to the farmer." To the private and market gardener, too, the loss due to attack is important, for the attack at the roots of Cabbage and Savoys often prevents

THE FOOL-PROOF ALLWOODII

IN these days of high wages and autocratic employes the single-handed gardener, or the employer who has to rely upon the services of one man to keep in order a garden which calls for two, begins to look round in the hope of filling up large spaces of unoccupied territory as cheaply and as effectively as possible.

A plant, therefore, which will give a glorious display over a long period is useful as a "cut" flower and, moreover, which possesses a delicious fragrance, will be welcomed by countless thousands of gardeners at the present time. Coupled with these virtues the fact that the plant is the hardest and easiest of all plants to grow, requiring as it does no attention for two years after it is once planted into position, should make its appeal to all lovers of a beautiful garden at a small expense.

Like most keen gardeners, when I come across a good thing, I am not happy until I have passed it on to others, so I feel that this new race of hardy garden plants which has been raised and developed by Allwood Brothers, the Carnation specialists, of Haywards Heath, Sussex, must no longer remain unknown to readers of this journal. I must confess that the name given to this new and delightful flower frightened me. *Dianthus Allwoodii* is the terrifying name which it will carry down to posterity. Those two 'i's at the termination of the name of the brothers Allwood will give a wrong impression to gardeners who are lovers of hardy plants. It is as bad as a child's parents christening the poor unfortunate "Clarence." I know all about that, because unfortunately I possess that Christian name. Such a name may be all right if the object of the bestowers was to make the boy grow up to fight his own battles. Nobody could go through his school life with a name like that without at least one fight per day. However, that is beside the point; but for some reason "ii" on any garden plant-name always conjures in my mind's eye something which has to be kept in heat and cotton-wool.

Shakespeare is credited with having written, "What's in a name? A Rose by any other name would smell as sweet," and *Allwoodii* might be substituted for the word "Rose" to prove that the poet knew what he was talking about.

I suppose if any gardener were asked to give his opinion upon the hardest, most easily propagated, fool-proof, sweetest-smelling hardy plant, he would plump solidly for Mrs. Sinkins Pink. For is it not hardy, fool-proof, and all the rest of it? A garden without a clump of this good old variety somewhere about is incomplete. Why, even people who have never done any gardening in their lives know it by sight. Their faces lighten, and a smile breaks upon their lips as they sniff the fragrance in the air, while the "I told you so" look comes into their eyes when they exclaim "Mrs. Sinkins" or more generally "Mrs. Simpkins!" In the near future they will substitute "Allwoodii."

Mr. Allwood himself informs me that *Dianthus Allwoodii* is one of the hardest of known plants; in fact, in his own words, it "has the constitution of a Shetland pony." It grows and increases in exactly the same manner as a Pink and requires similar treatment; but, unlike the Pink, which blooms for some three weeks in the summer, *Allwoodii* flower perpetually from early spring until quite late in the autumn. This long flowering period is probably inherited from one of the parents, for the *Allwoodii* is half Pink and half Perpetual-flowering Carnation; the flowers and habit of growth resemble the latter.

Of course, like most other plants, *Allwoodii* flourish best in an open sunny position, but they

are such accommodating plants that they will bloom anywhere except in complete shade. They are ideal as an edging when grown down the sides of a crazy or other path; in rockeries, banks or other dry positions they are equally at home. In fact, I am not overstating the point when I say that they will grow anywhere. Nor are they exacting as to soil; heavy, light or sandy, up they come smiling every time.

Early spring or autumn is the best time to put out the rooted cuttings from 3in. pots. If an unbroken edging is desired quickly, the plants may be put out at a distance of 6ins. to 10ins., but if time is no object, 1ft. or 18ins. is permissible. At such distances the plants may be left for two years without further attention, in which time they will probably meet and require to be propagated by means of layers or cuttings.

This new race of Carnation-Pink must not be confused with the old garden Pinks. The latter only bloomed once in a season, were poor in shape, and had it not been for their delicious fragrance would never have been tolerated. *Allwoodii* possess all the virtues which the old Pinks lacked. Colour, form and scent are now obtainable in these hardy plants which were previously only met with in the greenhouse varieties.

It will be seen that in *Allwoodii* we have an entirely new race of plants; no trouble and fool-proof. Plants which anyone can grow, and which can be increased with the ease and rapidity of the old garden Pink. Gardeners who have large beds of standard Roses and who previously grew *Violas* as carpeting plants beneath them might with advantage give these Carnation-Pinks a trial. Being shallow-rooted, while *Roses* are deep-rooted, one does not combat the other in the search for food and, unlike the *Viola*, which is rather a lover of moisture, the *Allwoodii* will flourish no matter how dry the season. In window-boxes or lawn vases they will give a continuous show of bloom from May to October. Even in winter their bright blue-green foliage is decorative.

In a bed or as an edging plant there is nothing which will give such a show for so little expense. In full bloom the bed or border is a drift of indescribable loveliness and perfume. Large plants may be lifted in the autumn and potted up, the plants being afterwards placed in a cold frame or greenhouse for winter blooming. A free circulation of air at all times should be allowed and the plants protected from frost.

Propagation is the easiest thing in the world, as *Allwoodii* root so easily from cuttings, pipings or slips in the usual way of propagating Pinks or Carnations. Cuttings should be rooted in July and August in almost pure sand, the plants being protected from strong sun and kept moderately moist while rooting. In about four weeks they may be potted up into 2in. pots or planted direct into position in the garden. When established the plant should be broken off at the sixth pair of leaves above the soil, otherwise the growth will quickly produce a single spray of bloom instead of making a bushy plant. Being of a dwarf habit, they require no unsightly sticks or ties, and should be allowed to grow away naturally after stopping. This advantage will be appreciated by anyone who has spent a morning among the old border Carnations. C. P.

A Booklet for the Beekeeping Beginner.—Messrs. Taylor's little eight-page booklet* should be invaluable to that very numerous class of

*How to begin Bee Keeping. Published by Messrs. E. H. Taylor, Ltd., Welwyn, Herts. Price 3d.

garden owner who wishes to keep bees not only as an interesting and profitable hobby, but for the service they render in ensuring the fertility of their fruit trees. It is to be feared that many a would-be beekeeper has been deterred from taking up apiculture by reading an appliance-maker's catalogue. These productions, like books on animal or plant diseases have rather an overpowering effect upon a novice. This pamphlet, then, which shows concisely how few appliances are really necessary to the beginners, how these few should be employed, and the simplicity of it all, should be of real service.

A Charming Rose Species.—*Rosa macrophylla*, though related to *R. Moyesii*, is at any rate, in the typical plant, very distinct from it in appearance, though it bears similar bottle-shaped fruit. Their curious appearance is produced by the persistent sepals forming a crown which swells out beyond the narrowed pip of the fruit proper. A rather prickly shrub, it has much the same stature as *R. Moyesii*, but the leaves are usually more than double the size, paler in colour and downy beneath. The flowers, too, though deeper than most species, are much more ordinary in colouring. Many forms closely related to this species have been introduced of late years. This is among the most desirable of Wild Roses.

A Trailing Coleus.—A *Coleus* that is ornamental all the year round is no means a plant to neglect. *Coleus Rehneltianus* carries out this programme to the full. Nay, more, for it chooses winter as its flowering season, and right away from autumn to late spring smothers itself with lovely light blue flowers. The habit is close and creeping, with leaves about 1in. in diameter, red brown in colour, strikingly edged with green. When the growths become covered with the dainty light blue flowers the plant is at its most attractive stage, and in addition to its appearance, advertises its presence by a delicious honey-like perfume. While a useful plant for growing in small pots to edge the staging, it is most beautiful, when thickly planted in hanging wire baskets, for suspending from the roof as the close, compact growth soon converts these into perfect balls of beauty, especially in winter, when first-class basket plants are by no means too plentiful. Stock can be obtained by sowing seed in brisk bottom heat at almost any period of the year while—once a number of plants is secured—further propagation is most readily carried out by means of cuttings struck in a propagating case in sandy soil. Look well over your seedlings before deciding which to retain for purposes of increase, for the plants vary in the depth of colour as well as the edging. The plants might well be given a trial outdoors, for there is but little doubt that they would form an ideal edging to beds of brilliant summer flowers.

FORTHCOMING EVENTS.

It is credibly reported that the leading Rose-growers, or at any rate some of them, realising the damage that has been done by unripe Dutch Roses, procured to replace a shortage, failing to survive the first winter, are going henceforward to guarantee their plants to be grown in Great Britain. Whether the non-survival of the "Dutchmen" be due to too early lifting and consequent "sweating" in transit, as some Dutch authorities incline to believe, or whether their failure be due to some other cause is of comparatively little moment. The move to supply British-grown trees is on every ground to be approved, and it is greatly to be hoped that the suggested guarantee will come to be generally adopted by reputable firms.

Sow Thinly.—The nurseryman might be thought to have every temptation to urge customers to sow thickly. Whatever the temptation all reputable firms with one accord recommend thin sowing and lavish thinning-out, yet every year there is far more Pea and Bean seed, for example, wasted by over-thick sowing than need legitimately be employed at all. In a few weeks' time rows of young Peas almost as thick on the ground as Mustard intended for salading will be noticeable in all directions, nor will they in the majority of cases be thinned out. It is hopeless in such circumstances to look for a good crop. What Peas are produced are seldom of first-rate eating quality, and the rows are productive for a very short time. No maincrop Peas should average less than 4ins. apart from plant to plant in each line of a wide double row, and in the case of exceptionally strong and bushy varieties, such as Gladstone or Autocrat, 6ins. between the plants is not excessive. If the ground is in good condition there is no occasion to sow much more thickly than the plants will ultimately be wanted to stand, but the case is, naturally, different in early sowings, where a certain loss must be anticipated and allowed for. Seeds sown henceforward will not come under this category, however, and there is no occasion whatever for thick sowing. The same thing applies to Sweet Peas, but since their flowering season should be prolonged, thin sowing is, if possible, even more desirable. Six inches between plants is amply close enough for cut-flower and garden decoration. The exhibitor,

of course, grows them more thinly still. Eight inches between Broad Beans in double rows, 8ins. between the lines and 2½ft. between the double rows are good distances, but some good gardeners prefer to space the double rows further apart and take a catch crop of, perhaps, Lettuces from between them. Probably flower seeds, notably hardy annuals, are more persistently sown too thickly even than vegetable seeds. They should be sown so thinly that the surplus ones may be withdrawn without damaging those which are to be left. Ultimately most annuals should be spaced about one-half their full height apart, but this is only a general rule. Such spreading sorts as Mignonette do better with more space than this would allow, while the Rhodantes—

to take but one example—which do not branch, must be left much closer to be effective.

Economical Cropping.—Thin sowing in the vegetable garden has the additional advantage of enabling the most to be made of the space at disposal. In the Pea trenches, for instance, Radishes may be sown as a catch crop. There will be ample room and time for them to grow to table size. Between Celery or Leek trenches, which should always be drawn early, seeds of any of the Cabbage tribes may be sown in drills for transplanting, as may Lettuces, also Wallflowers, which to make good plants for the spring should now soon be sown. Later on Forget-me-nots and Silene pendula may be sown in similar spots or Lettuces or spring bedding be pricked out.

Making the Most of a Little.—

Small enough in all conscience is the garden plot attached to the average suburban house or even to its "garden-city" cousin. Almost everyone would like a little flower garden in which to walk and sit and on which to look from the house windows. He feels, also, that he must raise a few home-grown vegetables and, if possible, a little fruit. The Editor cannot perform miracles, but he would suggest that space might be saved by including the Runner Beans as an ornamental feature of the little pleasure ground and by grouping the culinary herbs in the herbaceous border. Their fresh greens and greys are quite welcome there. Ofttimes an ugly tool-shed may be beautified in winter by the Yellow Jasmine (*Jasminum nudicaule*), or by the yet more beautiful and fragrant Winter Sweet (*Chimonanthus fragrans*). These have no particular beauty in summer, and a screen of Runner Beans—either Scarlet Runners or the pretty bicolor Painted Lady—may be employed; not too close to the shed, of course. Not nearly enough use is, in the average small garden, made of available wall space. Very often valuable space looking south is given up to one or two more or less trained Pears which, sadly neglected, fruit but seldom. What welcome winter blossom could have been grown here with the afore-mentioned climbers on the wall and *Iris nunguis* and other winter-flowering plants at the foot! or, again, what crops of Tomatoes, early Kidney Beans, or Pears on cordon trees! Even good crops of Peaches are possible there if someone is prepared to take trouble.

AN EXCELLENT AND GOOD FOLIAGED RHODODENDRON—
LADY CLEMENTINA MITFORD.

The GARDEN HYBRID RHODODENDRON

The writer discusses their hardiness and value in the garden and the best varieties for different seasons and gives hints on their culture.

At a time when there is something of a "boom" in new Rhododendron species and their hybrids, it may sound somewhat heretical to put forward the claims of the brilliantly coloured hardy hybrids with which we have been familiar from infancy. Heresy or no heresy, the writer firmly believes that were it not for the glamour always attaching to the new and rare, many of the new species which now receive such attention and "coddling" would receive short shift in our gardens. That is not to say that their introduction has been in vain. It is quite possible, even probable, that in course of time some of their better characteristics may be incorporated in hybrids as hardy as the hardiest now in commerce, but—such processes take time.

It is not to be supposed that the newest kinds of the so-called hardy hybrids, that is, those with the characteristic growth and magnificent truss of Pink Pearl, Alice or Mrs. E. C. Stirling are as hardy as the older sorts containing perhaps Catawbiense bloom; but that they will withstand very considerable cold we know, and we may even hope that, as they become acclimatised, they will stand more yet. Fortunately from one point of view, but unfortunately from another, it is many years since we had anything approaching a really severe winter. When such a winter has come and gone, we may, perhaps, have to revise our ideas of hardiness in many directions.

It is often urged against the Rhododendron that its flowering season is a very short one—so is that of the Gladiolus, for example. Yet people are found willing to lift, store, replant and tend Gladioli, while the Rhododendron once planted in suitable soil and situation, demands nothing but the removal of the seedpods after

flowering and a certain amount of watering in times of extreme drought.

The Rhododendron bed or border is furnished with deep green foliage, far superior to that of the Laurel, at all seasons of the year. Its shelter is admirable for many species of Lily, and if the magenta-purple shades be kept out it may well be interplanted towards the front with the lighter and more softly coloured forms of Azalea mollis. Good seedlings cannot be bettered for this purpose, selecting if possible those in shades of clear pink and pink tinged salmon, also the various soft yellow shades. The wonderful translucent colourings of the Azaleas does not, as one might expect, kill the more full-bodied tones of the Rhododendrons; it seems rather to enhance them. The Azaleas serve another purpose also. They give interest to the bed when, in late autumn, their foliage takes on tints of flame more brilliant than many flowers.

These hybrid Rhododendrons differ almost as much in habit as Dahlias or Chrysanthemums, a fact which should be borne in mind first when ordering and, afterwards, at planting time. It is difficult to suggest varieties, for there are so many really excellent kinds in existence, and so much depends upon the purpose in view and also whether they are required for massing or for specimen planting. Because it is fairly new and still not cheap, Pink Pearl is often planted as a specimen, but it is really inferior to many of the older kinds, of which Lady Eleanor Cathcart may be mentioned as a good example.

Many people like the massed colour only obtainable by using sorts which flower simultaneously but, considering the brilliance of the Rhododendron, it is doubtful if this is really necessary or even desirable.

Very early flowering kinds are the scarlet flowered Nobleanum (earliest of all), Handsworth Early Red and Handsworth Early White, the dwarf but brilliant Jacksonii and Cunningham's White and Cunningham's Blush.

The next group, which, following the practice with Potatoes, we will call second-earlies, includes what the writer considers the finest of all hybrid Rhododendrons—the rosy-crimson Cynthia. Were he restricted to one variety this would be the one.

In the same group, but a few days later, on the average, to flower, are those newer hybrids the flesh pink vigorous Alice, the better known Pink Pearl and the beautiful rosy-mauve Mrs. E. C. Stirling. Other kinds with the same flowering season are the bushy, red Broughtonii, which is excellent for specimens; that fine dark crimson Grand Arab, and the upright-growing, white George Hardy.

For "maincrop," to use once again the Potato metaphor, there is a wide selection, but the following are a few of the very best: The mahogany red Doncaster, most remarkably coloured of Rhododendrons, differs from Bagshot Ruby by being much smaller and more compact in habit and a little more remarkable in colour. Bagshot Ruby is, however, a fine grower and first-rate sort. To a lover of the clear bright shades, the peach-pink Lady Clementina Mitford, the salmon-pink Lady Eleanor Cathcart, already referred to, the salmon-rose Mrs. Holford, and that fine grower, the pale lilac Princess Hortense, make special appeal; but for those who like the deep plum shades there are Baron Schröder and the yet darker Joseph Whitworth, while the clear lilac-purple of the double-flowered fastuosum fl.-pl. is quite pleasing. Of whites there are plenty, of which the purest and one of the best is Mme. Carvalho; but the spotted kinds, Baroness Henry Schröder and Sappho, and the yellow blotched Mrs. Tom Agnew all have their uses. The last is especially valuable for backgrounds, as it is a strong, erect grower.

Other good sorts include the tall, blotched pink John Henry Agnew, the excellent, blush-white Gomer Waterer, the deep red Michael Waterer and the tall, rosy-red Frederick Waterer.

Red and white varieties conclude the season as far as these hardy hybrids are concerned, but, of course, in favourable localities the Chinese species and hybrids will considerably prolong the season. Of a dozen or more late kinds the following are perhaps the best: Alexander Adie, strong growing crimson kind; Mrs. John Kelk, bright red, excellent; the blush-white Lady Hillingdon and Mum and Pictum, both white kinds.

Is it necessary, one wonders, once more to emphasise that a good, lime-free loam really suits Rhododendrons better, at any rate from a garden standpoint where compact habit and masses of flower are desiderata, than the more usual peaty compost? Considerable experience has shown the writer that it is all but useless, whatever precautions are taken, to attempt to grow Rhododendrons on what are naturally limy soils. Cowdung and rotten leaves will most readily provide the necessary humus. For the first few years an annual mulching is desirable.

SHOWS THE VALUE OF THE SPECIMEN RHODODENDRON.

THE RIGHTS AND WRONGS OF WALL GARDENING

WHO that has that good gift of a crumbling old brick wall in the garden, or elsewhere within the home amenities, could fail to take advantage such offers for adorning with suitable plants? *Suitable plants!* Some of this work which has been done sadly transgresses

pile of Rochester Castle, Kent, it was personally sought and found growing and blowing at a dizzy height, attached to the crumbling mortar joints of the massive stone blocks, and a slip was secured which eventually became an interesting memento of the visit paid now many years ago. Hence it may be taken that the humbler members

MUCH FLORAL BEAUTY MAY BE OBTAINED ON A RETAINING WALL.

the simple ethics of wall gardening as one feels it should be. For instance, one example under notice for several years has been nothing but an additional source of labour and worry to the gardener in charge, and doubtless if he could have the last word on the subject it would be to make a clean sweep of the lot from the crumbling wall top and clinch the matter by sealing all up with a good coping of Portland cement.

Several scarlet Geraniums made their appearance on that particular wall top, apparently in pockets made for the purpose, with similar weeds (matter out of place), entailing a daily climb with the water-pot to eke out their short and not particularly merry lives may be called wall gardening, but one feels it to be a mistake. Even those long-legged Carnations, obviously from under glass, which might have struggled on without visible means of subsistence, as last seen, were staked up and most painfully prim. That seemed the last straw. All, or anything of the kind, suggestive of pretty constant labour and attention, or anything not able, once introduced, to go on for ever and fight it out unaided, comes not within the category of wall gardening from the true gardening point of view.

The very position is the birthright of some of the most interesting members of plant life, such as the heat-loving Houseleeks and the alpine Pinks—Pinks, perhaps advisedly. It may be questioned whether some, such as that gem of the alpine flora *Dianthus alpinus* would prove perennially at home; but as far as the reputed parent of the Carnation family, *D. Caryophyllus*, is concerned, taking the advice of the late Mr. W. F. Burbidge that it was possible to find it established high up on Bishop Gundulf's historic

of the tribe love the elevated site. Comes, too, the happy memory of a great cushion of *Dianthus superbus* hanging oft, over either side of a garden stone wall.

Wallflowers and Snapdragons are, of course, mere vagrants, but often well worth initiating for Nature to play the game, as she is doing (and kindly tolerated) on the dividing wall between a couple of town gardens, which is, for many months, a glowing mass with rosy pink and deep crimson Valerians. The professional eye may not view such with unqualified admiration, but it is another story with the less aggressive and more refined little *Erinus alpinus*, where not only an old wall top is covered with it, but every crevice and cranny over the whole face is ablaze each summer with its warm beauty. That is a rare example in an old-world spot of the ducal demesne of Carton, Maynooth, away in quiet Kildare. One of the sights of early summer, too, is the massive keep of one of the ancient feudal castles of the noble family of FitzGerald crowned with vagrant yellow Wallflowers near the above demesne, where by some happy chance they found footing after Cromwell's attempt to demolish it which prepared the way for their foothold some soft, up. Of Snapdragons in vivid hues comes a pleasant memory of Dr. Sherrard's historic house, Eltham, Kent, and a rather imposing arched entrance to the garden simply ablaze with their beauty.

On one occasion personal effort was made to form a collection of Houseleeks on a solid topped stone wall by removing here and there one of the smaller stones, putting in a plaster of cow manure in which a rosette of each of the more interesting species obtainable was inserted, much on the principle that cottagers of Kent were prone to

introduce, or occasionally replant, cushions of the medicinal *Sempervivum Tectorum* on the pantiles of a roof. Our specimens were the interesting *arachnoideum* and its fine variety *atlanticum*, *atropurpureum*, a fine form of which the late Mr. W. F. Burbidge, who was gratified with the planting, called *violaceum* in its lovely colour, and others. Eventually they all made nice cushions and became a very interesting phase of wall gardening. After a few years, on leaving the locality, the little Houseleek garden remained intact for the gratification of new tenants. A neighbouring garden at hand may not be forgotten with its wall, on which *Ethionema grandiflorum* flourishes in quantity, a plant or two originally introduced having seeded freely and yielded a prolific progeny wherever the seeds could get a foothold.

Dublin.

K.

'TIS THE WHITE ANEMONE

An appreciation of a gracious wilding which, in some of its more uncommon forms, inhabits many gardens, but which is itself a "pearl beyond price."

TO the Ranunculads, or Crowfoots, we owe many of our most beautiful or brilliant flowers, and it would be difficult to conceive our fields, our woods or our gardens without the many exquisite or showy plants this great Natural order provides. None, however, excel in beauty the Anemones, although many are more imposing in mien, such as the Larkspur, or more effective, such as the Clematis, whose sheets of blossom so much adorn the gardens of our land. Of the host of Anemones commonly met with in gardens, but few are native plants, but these are in themselves so charming and so interesting that they would do more than afford sufficient material for an article of a length suitable for these columns.

As we think of our British Anemones our thoughts naturally turn to the Wood Anemone, *A. nemorosa*, in all probability the only one truly indigenous to Scotland—a flower which is one of the most charming ornaments of our woodlands in the early months. Those of us who know aught of our countryside can, at command, recall with "the inward eye" the carpet of greenery which is so exquisite a feature of our woods in early spring—the tender, delicately "carved" foliage, and the chaste and fragile flowers of the Wood Anemone, whose dainty and fragile loveliness is so well epitomised by Shelley when he writes of

"One frail and fair Anemone."

It has drawn to itself the thoughts of other poets, and as we look, with delight, upon those spreading sheets of our native Windflower, nodding on their slender stems as the lightest zephyr sweeps athwart the woods, we recall such words as those of Lord Lytton, who wrote of this pioneer of spring in words which will appeal to all lovers of our native flowers:

"'Tis the white Anemone, fashioned so

Like to the stars of the winter snow,

First thinks, 'If I come, too soon, no doubt

I shall seem but the snow that has staid too long,

So 'tis I that will be the Spring's unguessed scout;'

And wide she wanders the woods among."

Clare has sadder thoughts of these fragile Windflowers, for he speaks of them as

"Anemones—weeping flowers,

Dyed in winter's snow and rain."

While Lewis Morris gives us a harmony of sadness and of gladness as he sings:

"Soon we shall pass
Together to our home, while round our feet
The Crocus flames like gold, the Windflowers
white
Wave their soft petals on the breeze, and all
The choir of heaven lift up their silent song
To the unclouded heavens."

Mrs. Hemans, who is now so little read, carries to us a thought of the shadier woods with their great tree trunks rising from among the flowers like the columns of some sacred fane:

"The silence and the sound,
In the lone places, breathe alike of Thee;
The temple twilight of the gloom profound,
The dew-cup of the frail Anemone."

From all these verses we miss, however, the note of jubilation with which the poets sing of the Poppy Anemones of other lands, which seemed to have borrowed from their brighter skies a greater share of brilliancy than belongs to our own denizens of the woods.

With all the beauties of the Wood Anemone heightened by and wrought into harmony with the environment in which it has been placed by Nature, it appears almost like sacrilege to transplant it thence to the narrow bounds of our gardens with their artificiality and restraints of cultivation. Yet the intense desire to possess the *rus in urbe*, inherent in all lovers of flowers "cabin'd, cribb'd, confin'd" in town or suburb

known even in the time of Parkinson, is perhaps the most admired of all white varieties of the flower. In foliage and growth it is the counterpart of the typical plant, but the flowers are perfectly double, the central rosette of segments or petals being surrounded by a circle of guard ones which give the flower additional beauty, rendering it more formal, it may be, yet increasing its interest to all. It is of purest white, and is equally easy to cultivate as the single form.

Even the Wood Anemone has its eccentricities, and among these is its production of a variety akin in its formation to the old-fashioned "Jack-in-the-Green," familiar to growers of Polyanthus and Primrose. This is the variety called *A. nemorosa bracteata*, and its distinguishing features are the leafy bracts which surround the flower like a ruff of green, oftentimes tinged with some of the white of the segments of the flower itself. It is a quaint little variety, although it has a tendency to revert to the common form.

Of coloured varieties, which are now rather numerous, we cannot do more than name a few, especially as some of the newer forms are not as yet procurable in the ordinary way from dealers in such flowers. The single form, with flowers faintly tinged with rose, and its double variety are fairly well known, and the latter is sought after by a few specialists, although it is not a whit more desirable than the double variety of snowy white. The variety Blue Bonnet is almost as blue as *A. appennina*, while the large-flowered *A. n. Allenii*, with lavender blue flowers, is late

THE PALE PINK-TINGED ANEMONE NEMOROSA BOSNIACA, ONE OF THE BEST FORMS OF THE WOOD ANEMONE.

and unable often to roam the woodland, has led many to endeavour to establish this simple flower in their gardens, there to enjoy the pleasure denied to them under happier surroundings; while even those who can with little effort, visit the Wood Anemone in its own haunts can find, in the several varieties, plants worthy of inclusion in their pleasaunces, howsoever great or small these may be.

Of the several forms of *A. nemorosa*, apart from the common one so well known as to require no description, that with double flowers,

flowering and charming, *A. n. Robinsoniana*, with its fragile cups of opalescent blue, many readers will know, and knowing, will allow that it is perfectly exquisite—exquisitely perfect.

When wandering through woodland in spring-time it is well to keep watch for any unusual form of this beautiful but, especially in some districts, variable plant. The species and all its varieties are easily cultivated in any light, loamy soil containing a good percentage of leaf-mould.

S. ARNOTT.

HOMELY FLOWERS

With the many glorious new races of plants some of the old favourites tend to become neglected, which is a pity.

FOR giving lasting satisfaction few flowers equal those that we generally call old-fashioned. The majority of them, too, are fairly long lived, and so afford this pleasure over a lengthened period. Furthermore, they are, nearly all, easy to grow. Forceful recommendations, are they not? For ten years I was responsible for the production of about thirty thousand bedding-out plants—for the summer season only—annually; these plants, including the cutting and seedling stages respectively, were handled three times before they were established in their flowering quarters. I mention numbers specially because there were two large beds in this big garden that were entirely filled with plants bearing fragrant leaves, flowers, or both, and I am correct in stating that the beds referred to were more appreciated than all the others.

Of course, I do not wish to convey the impression that I think other kinds of flowers inferior in every way and not worth cultivating; far from it, as I hold the view that there is room for all, and, as tastes differ, how fortunate we are in possessing such a wealth of variety—enough to satisfy everyone.

Isolated beds and others in odd positions are, I think, the most suitable for filling with "homely flowers." One comes upon them unexpectedly, and one's visitors are sure to be pleasantly surprised. A bed may be filled with a selection from the following kinds, and I have found old specimens, turned out of pots from the greenhouse, very satisfactory for the purpose: The lemon-scented Verbena, scented-leaved Pelargoniums, Heliotrope, Carnations, Pinks, Jasminum, Honeysuckle, Nicotiana affinis, Lilliums, Sweet Peas, all planted far enough apart to show clearly their individuality and to allow free growth to a groundwork of Mignonette. Near the edge of the bed there may be clumps of the Night-scented Stock (*Matthiola bicornis*) and Ten-week Stock. If available the bed should contain several specimens of Lavender. Of course, to contain all these plants the bed must be quite 20ft. long by 7ft. in width. By employing fewer plants a smaller bed could be just as satisfactorily furnished.

An informal bed would contain such plants as Hollyhocks, Delphiniums, Phlox, Chrysanthemums, Ox-eye Daisies, perennial Asters, Cornflowers, Dahlias, Poppies, Marigolds, Petunias, Zinnias, clumps of Sweet Peas, Sweet Williams, Aquilegias, with a fronting up of clumps of Pansies, Violas, Nasturtiums, Ten-week Stocks, annual Asters, and the pretty Virginia Stock.

The shaded border—it may be one near the plantation or overshadowed by some fine specimen trees—may be made most interesting if Saxifrages in variety, Honesty, Michaelmas Daisies, Foxgloves and similar plants, strong-growing by nature, are planted in prepared positions. G. G.

FORTHCOMING EVENTS.

March 22.—Wimbledon and District Gardeners Society's Meeting.

March 23.—Royal Botanic Society's Meeting.

March 24.—Paisley Florists' Society's Meeting.

MAGNOLIAS FOR THE SMALL GARDEN

There are few more beautiful small trees or shrubs than the Magnolias, nor, if a few simple requirements are attended to, many easier to grow.

THE novice with a small or not over large garden who consults a horticultural dictionary is not very likely to plant Magnolias. Heights of 60ft., 80ft., 90ft., even 150ft., are there mentioned as the limits of growth of different species and varieties. This notwithstanding, where shelter exists or can

conspicua, which, though it ultimately attains double the height of *M. stellata*, really requires less space when mature, inasmuch as it takes on, with age, the habit common to deciduous trees. This is an excellent species to train against a south or west wall, but it is valuable also as a bush as it has a pyramidal habit of growth and flowers

only real exception to this is *M. stellata*, which likes a more open root run. It is, in fact, fonder of peat than are Rhododendrons, and thrives in a compost half peat, half light loam. All Magnolias are impatient of drought. They are also impatient of removal when dormant. They should therefore be removed either when growth is starting in spring—as late as May will answer—or very early in autumn before growth has ceased.

The evergreen *Magnolia grandiflora* with its immense creamy-white flowers produced in late summer is a beautiful wall tree, and in our Southern Counties succeeds in the open, although, so treated, it grows but slowly.

THE YULAN, MAGNOLIA CONSPICUA, LOADED WITH GLISTENING CUPS.

be provided against rough winds, and, especially in the case of certain kinds, against morning sun striking frosted blossoms—some of the Magnolias are among the most useful and most beautiful of flowering shrubs. The word "shrub" is used advisedly, since even the large-growing Yulan flowers when quite small and grows quite slowly.

Perhaps the most beautiful of all Magnolias—certainly the most useful for the small garden—is *M. stellata*, still often called *M. Halleana* in gardens. It may in time in favourable situations attain a height of 12ft. to 15ft. or so, forming then a bush 20ft. perhaps through, but it commences to flower when still small enough to grow in a 5in. pot and grows slowly, if steadily, so that it takes many years to attain the size of a fair-sized Lilac. Gales, or ever fresh breezes, often damage the blossoms, so that it should be afforded as sheltered a site as possible. It is, however, very prodigal with its blossom, and the tree quickly recovers its appearance. It is in flower during the present month and in April. This irregular opening of the blossoms, which considerably spreads the flowering period without detracting from the appearance of the tree, is characteristic of Magnolias in general. The variety *rosea* differs from the type in having blossoms which are a delicate pink when they first expand.

Next in order of importance to the man with limited space at disposal is the Yulan. *M.*

while still quite young. The flowers, which have petals about 2ins. long, are pure white.

Magnolia obovata has flowers of about the same size, but it is looser in habit of growth and thinner of wood, and the flowers are purple and white outside, white within. This is the plant which is often listed as *Magnolia purpurea*. The variety *purpurea* is wholly purple without—a moderately hardy and valuable species, but chiefly notable as being the parent with the Yulan, already described of two excellent hybrids known as *M. Soulangeana* and *M. Lenei* respectively, the latter with broad, handsome foliage and huge substantial blossoms in which the petals are often as broad as long. The flowers are handsomely shaded without with purplish rose and glistening white within. Rather late to flower, it is seldom injured by frost.

Magnolia Soulangeana is, perhaps, better known than the last named and differs considerably from it, though it is said to have the same parentage. Very similar in habit of growth, it flowers later than the Yulan and differs from it in many particulars chiefly interesting to the botanist, but the rose-stained flowers and its later season of flowering render it quite distinct. The variety *nigra* has a habit of growth similar to that of the typical plant, if rather less vigorous with the more pronounced colouring of *M. obovata purpurea*. *M. Alexandrina* often seen listed, is but a form of *M. Soulangeana*.

Magnolias are fairly accommodating as to soil, but appreciate a sound loam in good heart. The

SOME NOT COMMON INDIGENOUS PLANTS

Now that the time approaches when flower lovers will again be haunting the hedgerows the following notes on native plants of interest seen last summer should be apposite.

SOME fine white flowering spikes of the common Bugle, *Ajuga reptans* were seen in early May in this district (Cleveland, North Yorks), also sparingly white flowers of the Bluebell, *Scilla nutans*, and quite a quantity of the white variety of the Milkwort, *Polygala vulgaris*; some of the larger flowering specimens of this *Polygala*, especially the rosy red variety which I have, are quite worthy of a place on the moraine or in the rock garden.

Early in June I had an interesting week-end in a locality in the North of England noted for its alpine flora; at an altitude of about 1,800ft. on "sugar limestone" formation, *Dryas octopetala* was very local and very dwarf, with small leaves (the variety known as *D. octopetala minor*, which also is found in the Irish station; I have a plant from the latter locality which sheds its leaves in the winter with me, and the larger-leaved type from the Alps does not appear to do so); the leaves are hard to the ground and there were very few flowers, these probably being grazed off by the mountain sheep which were in evidence on the ground. In the same locality was a dwarf *Antennaria dioica* with short-stemmed red flower-heads, certainly a desirable and pretty plant for the moraine if it would only keep dwarf at a lower elevation. I have seen no note of this variety referred to in the floras of the district that I have had access to, *Hippocrepis comosa*, on the same ground, owing to its extreme dwarfness, was almost unrecognisable; these plants hereabouts were just what you would expect them to be in an exposed position at an altitude of about 8,000ft. or so in the Alps. *Helianthemum canum*, with its small-leaved wiry foliage and dainty yellow flowers, the petals in the bright sunshine being very much reflexed, was sparingly associated with the above plants and more freely in another position on the same "Fells" some little distance away, but extremely local; stunted plants of *Draba incana* were fairly frequent; also *Arenaria verna*—this was more frequent and very fine along some of the stony tracks. In a damp position at a little lower level the rare *Juncus triglumis* was seen; unfortunately, owing to some of these plants having been transplanted in this locality by an ardent botanist many years ago, it is not possible to say with certainty that it was original; it was transplanted from a locality in which it still flourishes at no great distance away, but in an adjoining county. Local interference with rare native plants in this way is

hardly wise and the result can only be to throw doubt on all future records in the locality for the species so tampered with.

At a higher altitude, 2,000ft. or more, the pretty foliage and white flowers of the Clond Berry, locally known as "Knout Berry" or "Out Berry" (*Rubus Chamæmoros*), was fairly frequent, usually in somewhat boggy heaths associated with *Sphagnum* Moss. This plant is occasionally included in plant catalogues, and would be quite a desirable plant to have in the garden if it was possible to succeed with it at the lower levels. I have tried it, as also have others, but none so far as I know with any success; it is pretty both in flower and leaf—the latter especially when it assumes its rich autumn tints, as I once saw it in quantity by the side of Stake Pass leading from Wensleydale to Wharfedale.

A beautiful plant of the Moschatel (*Adoxa Moschatellina*), nicely fitted in under the shade of a large rock at an altitude of about 2,200ft., seemed to be very high for this plant and more than double the height it is given as reaching in the North Yorks flora. About the same level the only flowering plants of *Gentiana verna* (two) were seen; it had flowered quite freely on the lower ground earlier; in fact, owing to the dry, hot spring it was out and over much earlier than ordinary. I am afraid it suffered more than usual from visitors this year and, unfortunately, for the most part those who remove the plant are the least likely to establish it; it is not easy to the expert, and he usually, if he takes a rare or local plant either at home or abroad, is very sparing and careful to do as little damage as possible. It would be a disaster if a rare and beautiful native such as *G. verna* is, should become exterminated to all students of nature, not only present but future. A white-flowered variety was seen by a friend in this locality some years ago. It may not be out of place, taking into account the enquiries and notes on varieties of *Gentiana verna* that appeared in THE GARDEN last summer, to put on record that Correvon, in his "Plantes des Montagnes et des Rochers," includes the following named varieties: *G. verna chionodoxa*, *blanc pur*; *G. v. atrocerulea*, *bleu foncé*; *G. v. azurea*, *azur pale*; *G. v. grandiflora*, *G. v. rosea* and *G. v. violacea*; and a footnote states that all these forms were in cultivation at his garden at Floaire at the time.

Saxifraga hypnoides was fairly common at about 2,000ft., more especially on the southern slopes, and the pretty annual *S. stellaris* was frequent in damp places at a lower level; this was seen in damp ditches by the public highway.

At the pasture levels some lovely forms of *Viola lutea* were frequent and very noticeable on the wiry green carpeting. *Bartsia alpina* was occasionally seen in the damper parts of the high pastures. Some of the highest pastures, about 1,400ft. up, with south aspect were lovely with large masses of the Globe Flower (*Trollius europæus*) and the Bird's Eye Primrose (*Primula farinosa*), which were almost over at a lower level. Some of the *Polygalas* in these parts are very striking, and the interesting viviparous Knot Grass is fairly frequent over a wide area. One of the features of the higher meadows in June is the masses of *Geranium sylvaticum*, and by a roadside a plant of the white-flowered form was observed. Naturally, the Orchids are a special feature of the high pastures, but owing to the long continued dry weather they were not nearly so fine as usual. If not the most beautiful British flowering shrub, the Shrubby Cinquefoil (*Potentilla fruticosa*), certainly ranks very high; it is fairly frequent, and in places quite in masses, although not last year early in flower; the British shrub is one of the most desirable for the larger rock gardens and no

inferior to the many other beautiful shrubby *Potentillas* that have been introduced into our gardens from China and the Himalayas during recent years.

The distribution of this *Potentilla* is interesting; in Great Britain it is only indigenous in an area composed of parts of North-West Yorkshire, Durham and Westmorland on limestone, and in the West of Ireland, Galway, Clare and Mayo (which also are the only British localities for *Gentiana verna*); common in Canada and United States; sparingly on the Continent of Europe, one Scandinavian Station, one locality in South-East Russia and in the Pyrenees and Maritime Alps, the plant in the two latter localities is of prostrate habit and known as *Potentilla prostrata*. ("Distribution of *Potentilla fruticosa*," by Dr. J. W. H. Harrison. *The Vasculum*, Vol. II, pages 49-51.)

Towards the end of June in visiting Mount Grace Priory the white variety of the "Ragged Robin," *Lycinis Flos-cuculi*, was seen in flower in damp, peaty ground near the old Priory Fish Ponds, and at the same time the dainty *Trientalis europæa* was in flower in the upper part of the wooded slopes. This species was also in fruit at Birnam in Perthshire in September.

Interesting plants noticed on the coast sandhills at Redcar in June included *Erigeron acris*, *Lepidium Draba* (a sweet smelling white-flowered alien, which

I have also seen abundant on waste ground in the district), *Astragalus hypoglottis* (a pretty native which grows in dry alpine pastures); along the sandhills between Redcar and Marske in July provided the pretty Maidenhair-leaved *Thalictrum minus* fairly plentifully; it is quite a nice plant for the garden, but, unfortunately, too apt to abuse the trust placed in it by running about too freely in good sandy soil. Quite a pleasant surprise at this time were the masses of the beautiful *Campanula rotundifolia* that dominated many parts of the banks, especially where they had been distributed by trenches and sods taken off during the time of the military occupation in recent years. The flowers varied considerably both in size and colour, ranging from the typical blue through various shades of pale blue to white, some of the forms being not unlike the silvery blue form of *Campanula pusilla* known as Miss Wilmott; there was quite an appreciable quantity of these pale blue varieties but the pure white bells were only sparingly distributed. This British *Campanula*, with its numerous varieties, is worthy of more use in our rock gardens; it is always beautiful and carries the flowering period on well into August, and although it may seed freely, it does not seem like being anything near as troublesome as *Campanula pusilla* often is to control.

Middlesbrough.

T. ASHTON LOFTHOUSE.

LARGE-FLOWERED SINGLE CHRYSANTHEMUMS

THERE is an impression abroad that the single Chrysanthemum of exhibition type is being overdone; that, in fact, its size militates against its general adoption as a flower for the amateur's garden in autumn. The decorative effect, however, of these large disbudded singles can hardly be questioned, for they embrace a wonderful range of colour, from purest white through the entire range of those glowing autumnal art shades for which this beautiful exotic is justly renowned, and culminating in rich and brilliant shades of crimson. Combined with these attractive colours the flowers have also lasting qualities that force them upon our attention; further, they are carried on light, flexible stems of more than ordinary length, making them ideal for any floral work of a decorative character.

While a considerable amount of technical skill is called for in producing blooms of exhibition standard, flowers of high quality can, nevertheless, be produced with quite ordinary care and attention. Nicely rooted plants may at this season be procured from firms specialising in Chrysanthemums. These should on arrival be potted up into jin. pots, using a light compost of two parts good loam, one part each of leaf-soil and stable droppings (the latter being first dried and rubbed through a half-inch sieve) with half a part sharp sand. Mix thoroughly and pot the plants moderately firm. After potting stand in an unheated frame, keeping close for a few days and shading the plants during bright sunshine. After a week some air must be given and he gradually increased till they will bear full ventilation. Towards the middle of April the plants will require repotting into jin. pots, being immediately returned to the frame, which should now be given a position in full sun. Lightly syringe the plants overhead early in the afternoon and for the first fortnight shut up the lights about five o'clock. By May 1 plants of this type may be fully exposed to the weather on all occasions, except during periods of excessive wet or when there are indications of frost. From the middle to the end of the month the work of placing in their flowering pots must be taken

hand, and for this operation employ a rougher compost than that previously named, increasing the loam by one part, the others in proportion already given. The plants should be potted firmly, but not too hard, and care be taken that roots are not carelessly damaged in ramming.

Great care is always necessary in watering. The plants should never become too dry, and a sodden condition must also be strictly guarded against, the best and safest test being to sound the pots, when a clear, hollow ring will indicate the need of water.

Stopping and disbudding of the growths is a necessary though somewhat obscure detail to the uninitiated. Stopping is directed to removing the growing point of the shoot sometime in April, although some growers prefer to let the plants make a natural break; in any case this results in the "lead" branching, hence disbudding consists in reducing the number of shoots to be retained. At this stage three to four shoots are sufficient, and those at the immediate top should be retained. A further break will occur towards the end of June or early in July, and again two to three shoots are retained to each of the original growths. These are grown direct to the next bud, which is now selected, and all side buds and lateral growths are suppressed.

Details of summer treatment include staking and tying of the growths as necessary; then, after the plants are settled in their flowering pots, syringe with clean water on bright afternoons. From mid-July onward until the flowers expand, some approved fertiliser should be given as a stimulant and is best applied in liquid form.

Housing the plants is best governed by the weather, and may generally be taken in hand towards the end of September or early in October. A good practice before housing is to lay each plant on its side and thoroughly to spray the underside of the leaves with a weak solution of liver of sulphur, this being an excellent preventive of mildew. As the plants come into flower maintain a free circulation of air, as thereby the lasting qualities of the blooms are developed to the maximum.

An excellent selection of varieties of pleasing colours include Jessica, Sandown Radiance, Kitchener, Mavis, Reg. Godfrey, Lady Astor, M.P. and Supreme, all in shades of crimson or chestnut; Bertha Fairs, Bronze Molly and Edith Dimond, in apricot and bronze shades; Coronet,

Gladys Cooper, Lizzie Robertson, Sussex Yellow and Glorious, in yellow orange; Allie, Molly Godfrey, Margaret (Godfrey), Mrs. W. J. Godfrey and Mrs. H. J. Jones, in shades of pink; and Stuart Smith, Tom Wren, Mrs. F. W. Smith, Mensa and Flossie, whites. T. S.

previously named, and embraces *Asperula*, *Bartonia*, *Calendula*, *Calliopsis*, *Godetia* (dwarf sorts), *Gypsophila elegans*, *Iberis umbellata*, *Linaria reticulata*, *Malcomia* (Virginian Stock), *Nigella*, *Phacelia*, *Reseda* and *Viscaria*.

Whether annuals are sown in straight rows or clumps of irregular shape is immaterial, as with a little foresight, even when sown in straight rows in the first instance, it is tolerable easy to give the groups a broken or intergrouping effect, although, of course, the clump method is much more practical when this end is in view. The great point leading to success lies in thinning out the plants early and systematically; that is, in two or three operations; ultimately the plants should stand as far apart as half their average height. Then, as soon as the final thinning is complete, insert a few dwarf, bushy loughs among the plants, so that when in flower no evidence of this support may be seen.

With regard to the soil for annuals, this should be deeply dug and moderately enriched with farm-yard manure to which a dressing of slaked lime should be given in advance of sowing. Ground freshly turned just previous to sowing, is best dressed with steamed bone flour instead of lime, this being lightly pricked to the surface with a fork, using it at the rate of 1 lb. per rod of ground.

A beautiful section of annuals include those of a half-hardy nature—*Anagallis*, *Brachycome*, *Kochia*, *Nemesia*, *Nicotiana*, *Phlox Drummondii*, *Salpiglossis*, *Scabiosa* (Sweet, really a biennial), *Statice*, *Tagetes*, *Zinnia*, China Asters and Stocks of the Ten Week type. Annuals of this section are best sown indoors towards the end of March, and, when large enough, transplanted singly to prepared soil in unheated frames, where they are gradually hardened off for planting in their flowering positions during the month of May. Half-hardy annuals succeed in soil similar to that recommended for hardy annuals. It should be light and rich; the richness, however, is best tempered by an application of steamed bone flour a few days in advance of planting; the latter balances the growth and corrects the tendency to exuberant vegetation at the expense of flowers. T. SMITH.

A SHRUB FOR WET GROUND

Those searching for an altogether unusual little shrub for a really moist part of the rock garden would do well to make a note of *Rhododendron kamschaticum*. Not only is it a very beautiful little plant, but it adds a vast fund of interest to visitors by always pretending that it is not a *Rhododendron* at all. To begin with, it sheds all its leaves in autumn and stands quite bare all through winter days. Then it grows in low, dense tufts, and instead of producing its flowers in heads, these are almost always solitary, although one may sometimes find a pair together. These flowers are rosy-crimson in colour, the three upper petals being spotted and the whole surrounded by a green calyx. Another distinctive feature of the plant is its method of spreading by means of underground suckers which serve as a means of propagation. In spite of this, it is a rare little plant, and, once one has it, it is, if given suitable culture, long lived. It needs continuous surface moisture, hence the suggestion to plant in semi-bog, for it soon perishes where there is any risk of even moderate dryness. Choose a place sheltered from the morning sun and thus avoid the flowers being spoiled by its shining upon them when they are frozen. Plant in sandy peat with which a generous amount of chopped Sphagnum Moss has been mixed. Never forget the water supply and all will be well; but the penalty of drought is quickly paid in dead plants

ANNUALS IN GARDEN DECORATION

The treatment and conditions suitable for the different kinds

TO the older enthusiast in gardening it has long been common knowledge that in annuals we have long harboured angels unawares, for what we do in the greenhouse, as a matter of course, with a few pots of *Clarkia*, *Godetia*, *Schizanthus*, *Viscaria* and Sweet Peas can be as readily reproduced in the open garden on a larger scale, the main difficulty being to convince ourselves that the thing is worth doing. Let us, however, con-

selves to advantage over bushy sticks or any light, wire trellis-work

A section of annuals that luxuriates in hot positions, where the soil is rather poor in quality and not likely to become over-saturated with rain, includes *Dimorphotheca*, *Eschscholtzia* (biennial, but always most satisfactory when grown as an annual), *Linaria alpina* (perennial), *Calceolaria mexicana*, *Portulaca*s and *Nemophila insignis*. Then there are two annuals that ask for quite

FEW PERENNIAL PLANTINGS ARE MORE EFFECTIVE THAN THIS BORDER OF HARDY ANNUALS.

cede that the methodical and conscientious care that we expend yearly in raising China Asters, *Antirrhinums* and Stocks can be extended to cover the whole family of annuals, then the result will be an enormous gain to the garden both aesthetically and practically, and for ourselves an addition to our plant knowledge that will agreeably surprise us in the breadth of outlook that it entails.

In the decorative scheme of the garden the greatest success follows when distinctive positions are chosen and always with due regard to the plants' requirements. Gourds are important fast-growing annuals for clothing trellis-work and lightly constructed pergolas, and require rich, light soil in a sunny position. Sweet Peas are ubiquitous, but are best displayed in clumps, using bushy sticks or wire supports for them to cling to. *Ipomoea imperialis*, also a climber, will succeed in ordinary garden soil, while *Tropaeolum majus* and *canariense*, though grateful for some slight preparation, will, however, often give wonderful results in very indifferent soil; like Sweet Peas, the two last-named display them-

different conditions; the diminutive *Ionopsidium acule* prefers slight moisture in the soil and enjoys some shade during the hottest part of the day; while the other, *Linnanthus Douglasii*, is an annual that revels in cool, moist conditions at the root, with the vegetative part luxuriating in sunshine.

Annuals of gigantic stature are found in *Cannabis gigantea* and the various forms of *Helianthus annuus*, the first named having its attraction in the foliage. When employed together an excellent screen will quickly result, while the effect in late summer of the big Sunflowers standing boldly out from a mass of greenery presents quite a pleasing feature in the garden.

The annuals, however, which give the greatest service in the garden are those I define as border annuals; they are strictly hardy annuals and should be sown where they will flower, March being one of the best months to begin. I have made two groups; the first, embracing the tallest sorts, includes *Calliopsis*, *Centaurea*, *Clarkia*, *Delphinium* (Larkspur), *Godetia*, *Helianthus*, *Lavatera* and *Papaver*. The second group, being dwarfier, will require placing in front of those

CORRESPONDENCE

THE V.M.H. AWARDS.

YOUR article on the awarding of the V.M.H. certainly voices the feeling of many. When one considers what the family of Waterer have done for gardens by raising Rhododendrons and Azaleas without being given this recognition there is bound to be comment. But it is only fair to point out that the Council are not unduly generous to themselves. Mr. Dykes' book on the Iris and his work with that genus are alike remarkable. Mr. Wallace has undoubtedly raised the standard of show exhibits and also of a certain type of garden. Their omission from the list is probably entirely due to their close association with the Council. Generally speaking, those people whose work definitely influences horticulture, the collectors, the scientists, the hybridisers and the distributors of plants or of knowledge are the ones the public consider "deserve special honour at the hands of the Society."—**SCRUTATOR.**

[In the article referred to (page 87) names were mentioned only as examples. Our correspondent suggests others who have done exceptional service to horticulture. All these instances, however, serve but to throw into higher relief the futility of some recent awards.—ED.]

THE ROADSIDE GARDEN HEDGE.

I DO not know where Mr. Dillistone may live, but if he were to try and plant flowering shrubs on the roadside in this district he would be foredoomed to disappointment. Not a flower, not a bud, would be allowed to survive the hand of the destroyer. If he tried evergreen plants such as Escalloniás or even Eonymus, every branch that could be reached and broken off would find its way to London or the nearest town at Christmas or Eastertide. It is sad, but true, the wild flowers of our hedge banks are fast disappearing; no wonder, when we often see Primroses, Violets, etc., pulled out by the roots and allowed to wither by the roadside. The beautiful picture of *Viburnum plicatum* fills me with envy. Here it behaves very badly—"exists," but that is all. In four years the growth is about gins. *V. tomentosum* takes much more kindly to our soil; *V. macrocephalum*, said to be less hardy, is a mass of bloom annually on a south wall; and *V. tomentosum* var. *Mariesii* looks as if it would beat them all in a few years.—**HEATLEY NOBLE, Henley-on-Thames.**

SOME FINE KINDS OF SNOWDROPS.

THAT broad-leaved Snowdrop, *Galanthus Ikarie*, flowered early in February this season. Its leaves are a very glossy dark green, they bend outwards more than any other form, more like those of a *Stilla* than a Snowdrop. The flowers are large, well balanced, very pure white with a large spot of green on the inner segments. It is grown here in a south-east border under a greenhouse wall; it seems to like a warm situation. It is only found on the Island of Nikara off the coast of Asia Minor. The Straffan Snowdrop is one of the most charming of the family. It has a long period of flowering, which is characteristic of the caucasicus or plicatus kind. Each bulb, when strong, produces a second flower between the pair of leaves, so that when the first flowers wither a second array takes their place. In 1856 Lord Clarina brought bulbs of *G. plicatus* from the valley of Tchernaya in the Crimea, to Mrs. Barton of Straffan, County Kildare, among them came this distinct and beautiful variety. Mr. Streeter, the gardener at Straffan, tells me he gives a top-dressing of leaf-mould every second year to all

Snowdrops growing in grass—the result at Straffan justifies his methods. The Snowdrops are like a white quilt on the ground, and when their season is over they are replaced by Daffodils, which, in the damp climate and rich soil of County Kildare, grow from seed and some beautiful natural hybrids have occurred. Another Snowdrop from Russia, which came to Glasnevin from the Rev. Charles Digby of Lincoln, is a form of *G. plicatus*. Mr. Bowles says it is the best form. It was brought from the Crimea after the war, and has flourished in Mr. Digby's parish ever since.—**W. PHYLIS MOORE, Glasnevin.**

THE POMEGRANATE OUTDOORS.

FOR many years the Pomegranate flowered profusely on a south wall of my grandmother's house, Castle Hackett, County Galway.—**F. L.**

ADVICE WANTED.

I WONDER if you can help me with my *Cinerarias*. The strain is Sutton's Reading Gem, a hybrid between the usual variety and a Tenerife plant. My plants are healthy and look well, but they make so little progress. I wonder when their blooming season is. The hybrid is a pleasing new strain in some ways. It is much more compact, with small, serrated grey leaves. My greenhouse is seldom below 55°, and other *Cinerarias* find it too much. Perhaps some of your correspondents have had experience with it. I shall be very glad to hear what they have to say. Neither Messrs. Sutton nor the R.H.S. afford me any help.—**E. E. H. E.**

THE WILLING GARDENER.

IF other readers of your delightful paper enjoyed the article signed "D. N.," which appeared a week or so back, as much as I did, you will probably have been inundated by letters bearing on the subject. For ten years I had the good fortune to enjoy a similar experience to that of your correspondent, and the fact that "John," as I will call him, was of the jobbing variety only (my garden and means both being small) makes the keen interest in and love for his work all the more delightful. During all the time he worked for and with me, for we have spent many a long day at work together, he showed unflinching courtesy and consideration, entering into all my plans regarding colour schemes and grouping of plants with zest and interest. It is now some three years since a wise neighbour and friend engaged him as his regular gardener, but after his work is done he will often come and help me with his advice and suggestions, for although his successor is hard-working, he is not an expert. Only last summer, after spending some long time helping me in this way, he refused to accept the payment I offered him as due to him with the remark, "No, ma'am, this time is my own, and it's a pleasure to come and help you," and I felt that to press the point would almost have partaken of the nature of an insult. I could give many more instances of his thoughtfulness and kindness, but will not weary you; it is a pleasure to write this of one who has increased my love for and knowledge of things pertaining to the garden until it has become an abiding joy.—**E. M. C.**

SCORZONERA AND SALSIFY.

A QUESTION is asked on page 95 in an article upon Greenhouse Fuel as to the relationship between *Scorzonera* and *Salsify*. They are, indeed, closely related, and so closely similar in leaves, roots and their milky juice that they cannot

readily be separated botanically until they come into bloom. The roots of *Scorzonera* are, however, much darker in colour and often described as black, though the interior is white. The two plants are separated by many characters, which, to ordinary people, would seem insignificant, but are very important to botanists who have to note the smallest differences in order to divide up a family consisting of some 10,000 species or more. If the plants are allowed to flower in their second year it will be seen that *Scorzonera* has yellow flowers and many bracts overlapping one another in several series and enclosing the head. On the other hand, *Salsify* has purple flowers and only one set of bracts or scales surrounding the flower-head, while the roots are white. The late Mr. Alexander Dean once sent me a plant in bloom, asking for its name, whereas he might have guessed it was *Salsify* if he had seen it the first year. Botanically, it is *Tragopogon porrifolius*, but I fear I could not separate it from its cousin, the Goat's Beard (*Tragopogon pratensis*) unless both were in bloom, so closely similar are they the first year from seed.—**J. F.**

ALPINES AT MONT VENTOUX.

LOVERS of rock and alpine plants and all interested in their geographical distribution are indebted to M. Correvon for his interesting account (*THE GARDEN*, page 76) of a botanising and seed-collecting expedition to Mont Ventoux in Provence. Evidently the vegetation of this outlying bastion of the western Alps is profoundly interesting, particularly in regard to the low level to which certain plants descend, though often regarded as usually, if not exclusively, alpine—*e.g.*, *Douglasia Vitaliana*, *Androsace villosa*, *Saxifraga oppositifolia*, *Viola cenisia*, *Papaver pyrenaica*, etc. In that and other respects the flora reminds me greatly of that of the picturesque limestone chain of Sainte-Baume, some sixty-five miles to the south-east and approached from Marseilles or Toulon, though the latter range is about 2,000ft. lower than Mont Ventoux. The article points to a remarkable fact in the distribution of many alpine plants for which I have never heard an explanation. Why is it that we find in such southern mountains, and again in the Pyrénées, and to a less extent in the Maritime Alps close to the Mediterranean, alpine and sub-alpine species at lower elevations than in the cooler latitudes of the Swiss and Central Alps? I have collected abundant specimens and facts in proof of this. Is it possibly the fact that the ground in the high Alps is relatively much warmer than the air, as pointed out by Kerner and others, and the intensity and quality of the alpine light which causes plants to prefer the higher altitudes in the Swiss Alps to corresponding lower altitudes in which they are found in some of the more southern mountains? Or must we look to the vexed question of the origin of the alpine flora and its connexion with the glacial period at the close of tertiary times for an explanation? To find certain alpine species a few hundred feet above the sea in Scandinavia, or at sea-level in Spitzbergen is not surprising; but why are some of these plants and certain coniferous trees not seen at such comparatively low altitudes in the Swiss Alps with their longer winter and colder climate than that of the Pyrénées, Mont Ventoux and the Maritime or Ligurian Alps? We are told at Mont Ventoux such plants as *Papaver pyrenaicum* and *Douglasia (Androsace) Vitaliana* are abundant at the upper limit of the area reafforested—"a real Paradise for rock and alpine plants"—apparently this is below 1,850ft., where "the bare stretch of mountain" begins, with its "carpets of *Douglasia* . . . so thick, so enormous, that we must walk on them." One's first impression

is that M. Corveon forgot to convert metres into feet! But probably the figures are correct, and if so, they are a remarkable instance of a state of things that has so often puzzled me elsewhere. The summit is given as 5,800ft., whereas Baedeker gives 6,270ft. in the text or its equivalent of 1,912 metres in one of his maps; but this discrepancy is not serious, and it does not affect the chief point of this note. The strange thing is that various alpine plants do not get to the top of these much lower mountains in the South; whereas some of them, or closely allied species, frequently ascend to 12,000ft. or 13,000ft. in the Swiss Alps. As a matter of fact, alpine plants will grow at any altitude in the Alps, provided they can get a little soil in a situation free from snow for a few weeks in the short alpine summer. It should be added that notwithstanding the great height reached by a few plants in such Swiss mountains as the Matterhorn and Finsteraarhorn, the downward limit of the alpine and sub-alpine zones is considerably lower in the Bernese Oberland than in the Southern Alps of the Swiss Valais. In conclusion, we must not forget that a number of plants often seen at quite high altitudes and usually regarded by English botanists and visitors to the Alps as typically alpine, are not exclusively so, but are found at elevations of 2,000ft. or less, for example, in many parts of hilly France. To mention only a few, we have *Draba aizoides*, *Saxifraga stellaris*, *S. aizoon*, *Gentiana verna*, *G. ciliata*, *Swertia perennis* (grows near Paris), *Dryas octopetala*, *Anthericum Liliago* (frequent in sunny hills throughout the greater part of France) and the grass, *Stipa pennata*, whose long, feathery arms sometimes decorate the hats of Swiss and Austrian guides, and which, though occasionally growing in the alpine zone, is frequent in arid places in the plains and even reaches the neighbourhood of Paris. In this connexion we can ignore many of the numerous so-called "Alpines" of nurserymen's catalogues and rock-garden parlance, which, under no pretext whatever, can be called alpine, however suited many of them are to the rock garden. H. STUART THOMPSON.

ANNUAL FLOWERS FOR OLD FOLKS.

I HAVE a newly made flower garden and—I am an old woman—if I plant perennials the probability is great that I shall not live long enough to enjoy them in full perfection, nor make alterations or replace them where they fail. Last spring I did not plant perennials for the soil was not settled enough to receive them (luckily! for they would probably have perished in the subsequent prolonged drought in the shallow soil here), but, just to fill the borders for the time being I planted bulbs and sowed annuals. The result was such a surprising wealth of colour and continuous quantity to gather and to give away (one of the greatest joys of a garden), that I have decided to continue chiefly with A's and B's—to wit, annuals and bulbs. Why not? The bad old "bedding plant" days had some advantages. The beds were entirely dug up twice a year, and so all weeds were kept under and the soil could be cleansed and renewed. So shall my annual flower beds be treated! I can easily escape the tedious monotony of "bedded" borders by varying the annuals so as to have a continual succession all the year round, especially by providing some more or less permanent edgings, or, preferably, clumps of foliage, such as the silver grey of old-fashioned white Pinks for my fragrant border (this was a distinct success last year), and, perhaps, golden Pyrethrum, and certainly curled Chervil for others. Chervil is so accommodating (a "most reasonable plant," as Mr. Allwood would say), it will grow almost everywhere and keeps such a bright, cheery bit of fresh green through the

winter that, though its "proper place" is in the kitchen garden, I use it in my flower beds, and if they be further planted in late autumn, with some of Barr's variegated Kales, they will "carry on" from the Old Year into the next New One, till Aconites appear. The small cost of annuals, compared with "bedding plants," to say nothing of good clumps of perennials and the difficulty of obtaining these latter, is also a consideration, for if any annuals fail, it is not a serious loss, but can be "made good," generally, in a few weeks. There are plenty of tall things among annuals, and, of course, pillars of climbers can be arranged for. Sweet Peas were usually thus grown fifty years ago, so that annual borders need not be dumpy and dwarf. Some say "annuals are so short lived," but, apart from "bedders," if you come to consider the majority of perennials, you will find most of them, only flower for about three weeks in the year. Annuals have actually a longer flowering time upon the whole if sown thinly, allowed space to do their best, not "jammed together," as I

meaning the Oxeye Daisy, and some other plants; while Lucken Gowans were Globe Flowers. Gowan, then, is the Lowland Scotch name for the Irish and Gaelic "Gugan," a Daisy, a bud or a flower. The Gaels have so many words for the same thing that they have forgotten many of them. The European Globe Flower is not included in "Gaelic Names of Plants," by John Cameron, under any name, although the plant is plentiful in wet meadows and on the river banks in the Highlands.—HORTULANUS.

AN EASY AND FRAGRANT PLANT.

I DO not think that sufficient use is made to-day of the quaintly fringed and gloriously fragrant *Dianthus superbus*. Less neat and tidy than the Cheddar Pink (*D. cæsius*) it may be, but, apart from its charming and characteristic fragrance, it has a certain distinction quite wanting in many of the commoner rock Pinks. By the way, can any reader tell me the real difference between the

TUMBLING MASSES OF FRAGRANCE—DIANTHUS SUPERBUS.

grieved to see some in Hampton Court gardens the last time I went there. And, only think of it! What a delightful variety of fresh effects I shall be able to devise and enjoy every year! Yes! I feel sure that for children and for old folks, annuals are *the* thing! Where are those new seed catalogues? Let me begin at once to make out my list of orders!—ANNE AMATEUR.

GLOBE FLOWERS.

THE discussion of the names given to the Globe Flower on pages 69 and 96 are interesting from the fact that they show how changes come about when we try to read meanings into names that had their origin in a language foreign to our own. Linnaeus' name of *Trollius* is said to be derived from the old German word *bol*, meaning a globe. The translation of this gives us Globe Flower, which we can understand. Locker goulus, Lockin Gowan and Locker Gowans are spellings of words that have been handed down to us by many generations of people trying to read meanings into the names. The first part of the name is evidently English. The word "Gowan" is the Lowland Scotch word for the common wild Daisy. The same people speak of Horse Gowans,

old Maiden Pink (*D. deltoides*) and *D. graniticus*. Are the plants of the latter usually sold misnamed, or has the difference between the two species (?) become obliterated as with Duke of York and Midlothian Early Potatoes?—H. H.

ST. FIACRE.

[Many correspondents have written to explain, on various authorities, that the original *fiacres* were sent out from a hotel, hostelry or lodging-house which displayed a sign depicting, or a statue representing, St. Fiacre.—En.]

"THE GARDEN" AS A BOOK OF REFERENCE.

"THE GARDEN" for last year cost me 3s. 6d. to get bound, and it cost me a little over half that until about the second year of the war. No one book can equal a few—only a few—volumes of THE GARDEN for the helpful information contained in the varied experiences of different contributors, when I want to learn about any particular species and its treatment, to avoid, if possible, beginning with a failure—V CALDWELL.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Seed-Sowing.—This operation must be guided to a great extent by the weather and the nature of the soil to be dealt with. On one point no doubt whatever need be felt, which is, never be in too great a hurry to sow. When the soil is cold or sticky it is much better to wait another week, or, if that be not considered practical or expedient, it may be possible to try to arrange a sowing of some of the more pressing items in skeleton frames. Among seeds to be sown about this time and which may be accommodated in temporary quarters and then pricked out or transplanted we have Brussels Sprouts for main batch, more Lettuce, Cauliflowers and Cabbages, and, should the ground be quite unfavourable, more Peas and Broad Beans to serve as a succession. As soon as the soil is dry and workable, sow seed on a warm border of a few more Early Horn Carrots, Spinach and a few more Turnips, not forgetting Parsley, which should be sown in a convenient spot for quick and easy gathering.

Frame Work.—Give early attention to young Carrots and Turnips, and thin as necessary. It is quite unnecessary where there is a brisk demand from the kitchen to do much Carrot thinning, as that can be done quickly enough when the roots are of useable size, leaving the weakly ones to develop as a follow-on crop. Turnips, however, must be thinned to several inches apart, and this should be done early. It will be helpful with these crops, as with other early ones, to stir the soil a little and air freely when climatic conditions are favourable.

The Flower Garden.

Sweet Peas.—An outside sowing of this indispensable annual should be made now in thoroughly prepared positions. These plants will give a good supply of cut flowers or provide a display to augment the earlier plants which have been raised under glass and which must be planted out before becoming drawn. Where a show of Sweet Pea blooms is required in several positions over an extended period it is a good plan to allow of sufficient room for some seeds to be inserted thinly among the earlier plants when placing them in their permanent positions. These two operations may be done at the same time.

Cannas are extremely useful in the flower garden, and may also be termed adaptable inasmuch as they may be used to good purpose in the more formal portions as well as the less formal. A well placed bold bed of plants of good colour among which are some well developed spikes of *Lilium tigrinum*, *Fortunei giganteum* variety, is an excellent autumn attraction, particularly so if near water, as the added beauty of reflection may be enjoyed. The plants having been at rest should now be potted up in suitable-sized pots and grown on in a gentle moist warmth until nicely established.

The Hardy Fruit Garden.

Bud Protection.—Small birds are often troublesome among the buds of Gooseberries and Red Currants just as they are plumping up, and as netting is a somewhat elaborate check to bother with, some more easy and simple method may be found sufficient, such as spraying or dusting the bushes with soot or lime when they are a little damp, or by syringing the bushes with some approved insecticide, recommended for the purpose, which will render the buds distasteful.

Apricots.—The blossoms of the Apricot are usually the first to greet us among the outside fruits, and their early opening renders them extremely liable to damage by frosts. See that a protective is in readiness for immediate use, such as thin blinds, or, where this cannot be arranged for, stretch a double thickness of netting over the trees. An isolated tree can be dealt with by having a few light evergreen boughs placed among the apricot branches.

Fruit Under Glass.

Late Vinerias.—As soon as the buds commence to swell the bushes should be kept closer and similar treatment afforded as for earlier Vines. On cold nights it will not be necessary to introduce much fire-heat for a start, but a warming of the pipes creates a genial and favourable atmosphere. Any top-dressing of the borders contemplated should be done at once.

H. TURNER

(Gardener to the Duke of Northumberland.)
Albion Park Gardens, Guildford

The Kitchen Garden.

Early Turnips.—Immediately the ground is suitable, small sowings of early varieties should be made. Select a portion of the garden where the soil is light and warm. Stiff, clayey soil is not suitable for the production of Turnips of fine quality. Sow in drills 6 ins. apart and about 1 in. in depth. Cover the seed lightly, running the rake over the bed to give a neat appearance. Early Snowball and Early White Milan are excellent sorts for a first crop. After the young plants appear an occasional dusting with soot will prove a deterrent to the ravages of slugs or birds. Keep a number of feathery Spruce branches at hand for convenience in covering the bed should late frosts prevail. This precaution often saves the early crop and precludes the likelihood of stringy bulbs so readily caused by the growth being checked.

Vegetable Marrows.—Seed should be sown now so that a number of plants may be available for planting on partly spent hot-beds and thus ensure an earlier supply of Marrows. For frame work the small fruiting varieties are preferable, maturing more quickly and proving of more adaptable size for kitchen purposes.

Peas.—Sow seed at regular intervals for succession, using second early varieties at this time. Gradus and Early Morn are Peas of high quality and heavy croppers.

Asparagus-Beds.—Clear off the rougher portion of the winter litter and give the beds a dressing of salt. Top-dress with fresh soil, and make trim by digging and reforming the alleys.

Autumn-Planted Cabbages.—Give these a pinch of sulphate of ammonia, afterwards running the cultivator through between the rows. This will be found considerably to accelerate growth.

Fruit Under Glass.

Vines.—Continue to disbud as required, reducing to one on each spur as soon as the bunches are visible. Growth will then be more noticeable, and an increase of warmth may be given so that full and proper development of the bunches may be ensured. Exercise care in tying down the laterals, and stop same at the second leaf beyond the bunch. Where the Vines are in flower keep the atmosphere fairly dry. Give the rods a sharp tap about midday so that pollination may be assisted.

Peaches.—In the earlier houses disbudding and thinning of the fruits will be the principal work. Do not thin too severely, as there is always a likelihood of a number of fruits being cast after the stoning period. In disbudding the young growths leave one or two near to the base of each bearing branch as possible, tying each shoot carefully as growth develops. Syringe freely morning and afternoon, taking the chill off the water before using. Test the border occasionally to see that root requirements regarding moisture are not neglected. Until the stoning period is past the day and night temperatures should be 65° and 60° respectively.

The Flower Garden.

Sweet Peas.—Make a sowing in the open now on ground which has been given generous attention during the autumn. Sow thinly and thus encourage sturdy growth. Dust with soot immediately the seedlings show through the ground and so guard against the ravages of slugs.

Carnations.—Where plants of these have been wintered in frames they must now be transferred to their flowering quarters. Carnations greatly enjoy the addition of wood-ash or burnt refuse to the soil, so where this is available have it lightly forked in when preparing the bed. Seedling plants growing in nursery borders should also be moved to the flower garden at this time. Layers may be planted about 12 ins. apart, but more space must be allotted those raised from seed, as they are generally larger plants and of more vigorous growth.

Clematis.—Among hardy climbers no plants equal the Clematis in variety or beauty. From now till the end of March is a favourable time to plant. Being gross feeders, they revel in ground that has been enriched with well rotted manure. Should the natural soil be devoid of lime, some old rubble should be added. *C. Jackmani* is eminently suitable for arches or pergolas, and should be pruned hard back this month. *C. lanuginosa* is a most charming plant, flowering

from July till October. This variety flowers from the previous season's wood, so only requires thinning and tying in of the young growths.

JAMES McGRAN,

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Chrysanthemums.—Cuttings of varieties suitable for growing in small pots should now be rooted. They are invaluable for furnishing the stages of the conservatory as well as for decoration in the dwelling-house. At this time the cuttings can be readily rooted in a cold frame. They should be potted on until they are in their flowering pots, 6 in. pots being a suitable size. They should be stopped or pinched several times to induce a bushy habit, and well grown specimens should carry about nine to one dozen shoots. When well established in their flowering pots they require strict attention as regards watering and feeding if they are to retain their foliage right down to the pots. For this method of cultivation it is important to grow the right varieties, as all sorts are not suitable for this work. All the Caprice du Printemps type are excellent for this purpose, Kathleen Thompson being one of the best of the set. Other good varieties are Baldock's Crimson, Blanche du Poitou, Framfield Pink, Heston Pink, Heston White, Lady Stanley, Middle L. Charvet, Market Red, Soleil d'Octobre and Yellow Cheer. Some good singles are Mrs. Buckingham, Ladysmith (still one of the best for this work), Joan Edwards, Kitty Bourne, Caterham Bronze, Mary Morris, Queen Alexandra, Sussex Yellow and Daret's Jewel. The latter variety should be grown three in a pot, as its habit is rather slender. Earlier-rooted varieties should be potted on as they require it.

Streptolol Jamesoni is worth planting out in a sunny position in a cool conservatory. One hears frequent complaints that this plant does not flower freely, but this is usually due to the fact that it is not freely exposed to plenty of sunshine. It is easily propagated by means of cuttings, and makes fine large specimens if grown on in large pots.

Begonia manicata.—This beautiful winter-flowering Begonia is a very old garden plant, being introduced from Mexico in 1842. By present-day cultivators its merits do not seem to be fully recognised, and when seen its cultivation seems to be misunderstood, at least when in flower; then one generally sees it in a stove temperature, in which the flowers come pale in colour and only lasts in flower for about three weeks. On the other hand, if the plants are placed in a conservatory—when the flowers commence to open—with a temperature of 45° to 50°, they come a beautiful colour and last in flower for three months. It is easily propagated by means of cuttings during April or May, and should be grown in 7 in. pots the first season, when it is useful for furnishing the stages. If grown on in 10 in. or 12 in. pots the second season, it makes large specimens some 6 ft. high with great sprays of rosy pink flowers. There is a variety with maculated foliage and another with wonderful crisped leaves.

Begonia coccinea is another fine greenhouse Begonia which makes a fine large specimen, and is very beautiful if it can be planted out and trained under the roof glass. Begonia President Carnot is seen to best advantage when grown in the same way, although *B. Luzerna*—somewhat resembling *B. President Carnot*—is a much better plant for the greenhouse, and is very fine when planted out and trained up a pillar. The old and beautiful *B. fuchsoides* is also seen to best advantage when planted out and trained against a back wall.

Hibbertia dentata.—This beautiful evergreen greenhouse climber has been in flower for some weeks now. Its dark yellow flowers, which are some 2 ins. in diameter, are very striking. The plant is easily propagated by means of cuttings or seeds, and it usually ripens plenty of good seed.

Hidalgoa Wercklei, generally known as the climbing Dahlia, is another beautiful greenhouse climber, but does not flower freely unless it is allowed full freedom of growth and full exposure to plenty of light and sun.

General Work.—Prick off seedlings of all sorts before they become crowded. Rooted cuttings should also be potted off before they become drawn and weak, shading them from bright sunshine until they get away at the root.

WITH Eastertide but three short weeks in front work in the garden takes on even greater urgency. The planting season made a very late start, and although the winter has, on the whole, been propitious, there are many planting programmes yet incomplete. Fortunately the lengthening day and the advent of "Summer Time" on March 26 allows overtime to be worked, but the pressure of routine tasks greatly curtails the time which can be devoted to new planting and alterations.

The Inter-nodal Cutting.—It is rather strange that so many otherwise excellent amateur gardeners take it for granted that all cuttings should be taken immediately below a joint (or node). Carnation and Pink pipings form an exception with which many amateurs are familiar though these are not, properly speaking, inter-nodal cuttings or indeed cuttings at all. Quite as good, if not better, results may be obtained from cuttings taken at the joint in the usual way and, of course, split to provide a surface for the roots to break from. Inter-nodal cuttings are essential if good plants are to be obtained of Fuchsia, Coleus or Tuberous Begonia. They are also largely utilised to propagate the various species of Bamboo. They are easier to make than the nodal ones so that the preference of some plants for this form of propagation should be rather a matter for congratulation than otherwise.

The Bedding Zonal.—The Zonal Pelargonium or Geranium, as it is still often called, is not used for bedding-out to anything like the extent it was even in 1914; certainly but a very small fraction of the number of plants are now employed for this purpose which were utilised, say, two or three decades ago. The "Zonal" has, none the less, its uses and it often happens, at this season, that the gardener would like a rather larger stock than he in fact possesses. There is still time to remove and strike the tops of strong and established young plants or, of course, to take more cuttings from stock plants. If the cuttings now to be rooted are to produce plants serviceable at bedding-out time, it is, however, essential that their natural resources be conserved to the utmost, so that they may root quickly and grow away with all possible rapidity. A sharp

knife should be used carefully to remove the scales which protect each joint, but no leaves whatever should be trimmed from the cutting before insertion. The petiole of the bottom leaf and possibly of the second one will be buried in the rooting compost and the bottom leaf may, very probably, wither before rooting is complete, but it will, in the meantime, have assisted very materially in the establishment of the young plant. The actual striking must take place in a clean sharp medium, but, once rooted, the young plants should be transferred without delay to zin, pots filled with moderately rich but not too light compost.

Drought and Fertility.—Should the present season be at all normal, gardeners may hope to derive benefit from the unfavourable conditions which prevailed last summer. It is generally accepted that drought has a fertilising action upon the land, a fact which is utilised by the farmer in his system of working fallows. Quite apart from

A Charming Anemone.—Some time before our native wind-flower makes a carpet for Nature's mass-planting of Bluebells, colonies of the bright blue *Anemone blanda* will have made beautiful the gardens where it is employed. The knobby root-stocks of this beautiful blue species do not produce the masses of flower and foliage which characterise the Appenine species some weeks later, but if planted thickly they form a rich blue carpet very beautiful to behold. A soil containing a large percentage of leaf mould suits them best and also a little shade is appreciated. If care is taken in weeding among them hosts of self-sown seedlings will augment the colony, but it is perhaps better to collect as much as possible of the seed, to sow it in pans and to place it in a cold frame where it will then germinate comparatively quickly. Should the seed be kept if only for a week or two it will probably take a full twelve months to germinate it. Some of the seeds will, in any event, self-sow themselves, as, in common with most other genera

of the Ranunculaceae, the *Anemones* quickly shed their seeds when these are ripe. The same precautions as to seed saving and sowing apply also to the Appenine Windflower (*A. apennina*) and to the *Hepaticas* (*A. Hepatica* and *A. angulosa*), of which the latter is larger and finer than the well known old favourite, but tends to be a little later to flower. There are several very beautiful forms of *Anemone blanda* but though easy to grow and very beautiful they are comparatively seldom seen in gardens. They range from pure white to velvety purple and include rose shades. Perhaps the most remarkable is the variety *scythinica* of which the blossoms are white within, blue without, thus producing an effect

MOST WELCOME AT THIS SEASON—THE AZURE PLATTERS OF ANEMONE BLANDA.

this, many gardeners will have noticed that dung applied to the soil rather late in the winter of 1921-22 has hardly disintegrated at all, so that they may expect to derive some benefit from it during the coming summer. It is probable that other not over-rapid fertilisers, such as basic slag, bones and "super-phosphate," were appropriated to a far smaller extent than usual. The winter has been favourable and vegetation now is backward—always a healthy sign—so that the gardener has every right to look forward with renewed hope to the coming season.

comparable to that of *A. nemorosa* *Robinsoniana* but with a stronger contrast of colour.

The Rock Garden will, in a very few weeks, be at the summit of its glory. It behoves the plant-lover now to go over his treasures and to see that choice plants are not in danger of being smothered by more rampant species nor choked by insidious weeds which have established themselves in crevices from which they can only be dislodged by pulling down part of the rock-work. Any "tidying up," however, should be done circumspectly or the natural appearance of the garden will be destroyed

SPRING TREATMENT OF LAWNS

How many lawns of all sizes lack that finish which makes a well kept English lawn the admiration of the world.

THE season has come round when the lawns claim a good deal of the gardener's attention. There is nothing so essential to a restful and satisfying flower garden as a well kept sward. Whether this takes the form of one or more fairly extensive formal lawns, suitable, it may be, for lawn games; whether the sward be quite informal in shape, contour and arrangement—a restful stretch of verdure leading the eye to the surrounding planting; or finally, even though, as must be the case in many small gardens, the turf is only used to form paths between beds and borders, it is of the utmost importance that it be well kept.

Even on a lawn which makes no pretence to being level, which in fact swells gradually to embrace the plantings which surround it, local hollows, such as are occasioned by uneven settling of the sub-soil, are very objectionable both to see and to walk over. There is still time to lift these patches to make up and to relay; but the

work must not longer be delayed. Most troubles with lawns, apart from the grass dying away in shady positions—of which more anon—probably originate from bad making in the first instance. An exception to this statement is debility in old lawns brought about by neglect. A symptom of the conditions subsisting is, of course, the presence of moss. Scarifying the surface to aerate the clogged-up soil and a dressing of good lawn sand will often work wonders, but it is advisable to take steps to supply more permanent nourishment by dressings, during the following winter, of bone meal and horse dung. It has become fashionable to recommend basic slag for renovating lawns. This is very effective if a strong plant of Clover is wanted, but it is to be feared that many people apply this particular fertiliser without realising this or wanting Clover in the least. Clover is, of course, intolerable in a tennis lawn, since it stains the balls so badly; but, in addition to this, it gives a patchy appearance

to the sward. It is sometimes recommended because it remains green in drought, but as it is not possible to get it to form an even carpet, the green oases merely serve to accentuate the yellowness or brownness of the cloverless patches.

It occasionally happens that a very old lawn will quite fail to respond to any less drastic treatment than relaying. In such case it is necessary to remove and to replace by new the soil to a spade depth. It is probable that such worn-out lawns have, at some time, been maltreated. The roller has with many gardeners become a fetish. They appear to think that the roller is an efficacious tool for removing local inequalities. To have any such effect it must necessarily be applied when the lawn is really wet, and any levelling it effects, which is small, is effected by undue compression of the soil. Lawns so treated do not, as a rule, grow a good type of grass, and they are not seldom infested with moss. Obviously, no surface application of fertilisers can correct a want of porosity in the soil. After the winter, especially in districts where much frost has been experienced, a certain amount of consolidation is, of course, necessary, and this is best applied with the roller, but care should be taken to see that the lawn is not over-wet.

Unless reserve turf is grown to repair bare places, which is very seldom the case in private gardens, it is now too late to patch with turves; but if good seeds be procured from a reputable firm to whom the peculiarities of the soil have been explained, this will be no hardship. Where re-sowing is to be carried out, the surface soil should be broken up several inches deep, but unless it has been much trodden when bare and so soured, it will be better not to replace it, as new soil so brought in oftentimes is full of pernicious weed seeds. Always sow lawn seeds thickly—2 ozs. to the square yard is a fair quantity to allow. Protection from birds must be afforded, either by the use of black cotton stretched back and forth across the re-sown patch a few inches from the ground, or, if, owing to the size of the re-sown area, this is impracticable, by some form of bird scarer, such as feathers or red twill on strings.

Thin places may generally be renovated without re-sowing if a suitable chemical manure be applied. The composition of this should vary considerably with the class of soil. Several firms now make a speciality of lawns, their grasses and several requirements, and the special fertilisers they supply for different soils may be relied upon.

Lawns mossy through poverty have already been described and the simple treatment necessary to eradicate the moss, but where the trouble comes, as it often does, from insufficient drainage, the case is different. It is now too late, however, to undertake drainage operations, and a dressing of lawn sand, though only a temporary measure, will more than repay its cost in the improved sward and easier cutting during the present season.

From now onwards much time will necessarily have to be devoted to mowing. The more closely mown the sward is kept, the smaller the chance that coarse, undesirable grasses have of persisting. The finer lawn grasses tiller and seem to luxuriate under the lawn-mower, but this is far from being the case with the coarser grasses more appropriate to meadow land. Even here, however, a word of caution is necessary. The lawn-mower should not be used when the grass is wet. Were this

MUCH OF THE CHARM OF THE GARDEN ALWAYS CENTRES IN BEAUTIFUL GREENSWARD.

point borne more steadfastly in mind, many of the worn-out patches seen on lawns would be things of the past.

It is quite impossible properly to maintain a lawn without an efficient lawn-mower. Where the sward is of any extent it may probably prove profitable to employ two types. The roller type has the advantage of rolling as it cuts and does not damage the surface of the lawn when it is on the soft side—as already explained, lawns should never be cut when really wet. Moreover, the roller machine cuts easily to the extreme edge of the lawn, whether against beds or paths, which, without a special and not over-satisfactory attachment, the lighter type of machine without a front roller cannot do. It may well be asked what possible service, where the heavier type is available, these lighter machines can render. As

a fact, where there is any extent of lawn to traverse, they are very useful, especially when the lawn is quite sound and dry in summer-time. They are much lighter not only in dead weight, but in draught, and whereas, in a good type, the driving wheels are large, an exceptionally good speed is imparted to the cutters, so that, under the conditions described, it should be as easy to push a 17in. high wheel American pattern machine as a 12in. one with the front roller, and this without any loss of efficiency.

The besom which, at this season, should always be applied to spread worm-casts before rolling or mowing commences will also serve, if thoroughly applied, to remove the small stones which play havoc with the perhaps newly-ground cutting cylinders of the machines.

WATER-LOVING HARDY PRIMULAS

The comparative values of the better species and varieties are discussed, and a cheap method of procuring a stock indicated.

P RIMULA JAPONICA was for years in a class by itself as a hardy, bog-loving Primula. Hardy as the proverbial Cabbage and obtainable ultimately in a variety of colours—deep crimson, bright rose, pale rose and a not too pure a white—it was indeed a valuable plant for wet ground, especially by the waterside. One still remembers how fine we thought it until the advent of the stately *Primula pulverulenta*. Similar in its typical colour—a deep wine-crimson—the newcomer made the thick-set *P. japonica* look unbelievably plebeian, for it had an “air” not easy to describe. Taller than the longer known plant, more slender of stem and its stems heavily clothed with white farina, with a graceful arch to the foliage instead of the healthy, but not engaging, leaves of the Japanese plant, and a beauty of form and spacing about individual blossom, whorl and spike not possessed by the other, little wonder it made an impression.

Many new plants have since been introduced, but in its special sphere *Primula pulverulenta* still reigns alone. In one way only is it inferior to *japonica*—very seldom does it reproduce itself from self-sown seeds. It succeeds in a fair amount of shade; even “drip,” so deadly to many plants, appears not greatly to trouble it. Flooding in winter with several inches of water, it seems not to resent at all.

Probably the upsetting conditions involved in a total change of environment may have stimulated it to sport. Certain it is that it had been but a little while in commerce when a blush pink form revealed itself and was christened Mrs. R. V. Berkeley. This plant is sometimes described as cream or even white flowered, but it assuredly neither is nor was (the writer saw the plants to which the R.H.S. award was given) either one or the other. A little later a sport of a much deeper shade of pink with a hint of cerise in the colouring made an appearance. This had (and has) an orange eye instead of the yellow one characteristic of Mrs. R. V. Berkeley. This form, which is more robust than the paler one, received, some years ago, a first-class certificate from the National Auricula and Primula Society under the name Lapworth Rose. It does not seem yet to be as well known as it should be, or, rather, it is often confused with the older and paler form.

It is a pity that more selection is not usually attempted with hardy Primulas. To take *P. pulverulenta* as a case in point, by re-selection it is possible immensely to improve one's strain,

both as regards colour and form of blossom. There is no white form of this plant so far in commerce, but the writer predicts that when, sooner or later, one turns up it will be a pearly white as unlike

of lilac and somewhat pulverulent stems, is not so fond of water as those already mentioned, nor is it in itself a particularly valuable plant, albeit the parent of some pretty hybrids, mainly with *P. Bulleyana*.

The Sikkim Cowslip, *P. sikkimensis*, is another water-loving species of, unfortunately, little more than biennial duration. A patch of it is, however, worth a little trouble, for the sulphur yellow bells are very beautiful.

Yet another crimson-purple species calls for attention. This is *P. Poissoni*, another of the whorled (*Candelabra*) section, which has glossy, slightly toothed leaves quite distinct from the rather Primrose-like foliage of all the others so far described. The flowers, too, approach more nearly to magenta than do those of *P. pulverulenta*. Growing only to a height of 12ins. or so, it is a valuable plant for a damp corner.

Most gardeners know the beautiful *Primula rosea*, but it needs shade and a cool root-run rather than superabundant moisture, though it will tolerate a fairly damp soil. Rose is a variable colour in gardens. Very seldom is it applied to so bright a shade as gladdens the eyes that rest on *Primula rosea*. (Contrast this colour with a rose-coloured *Pyrethrum*!) This plant also has smooth leaves, a peculiarity it shares with the quiet but beautiful *P. involuerata*, also a water-lover, which, on 6in. or 8in. long stems, bears

MASSED PLANTING OF PRIMULA PULVERULENTA MRS. BERKELEY, WITH THE TYPICAL CRIMSON PURPLE FORM BEHIND.

the white *P. japonica* as the translucent pink forms are to the rose form of the “Japanese.”

Of the other water-loving Primulas the best is, perhaps, the clear yellow *P. helodoxa*. Though it lacks subtlety of colouring, it is remarkably effective when massed. It, too, has slenderness and dignity, though it wants the imperial carriage of *P. pulverulenta*. Why, one wonders, may not this latter plant have an English name? More subtlety of colouring attaches to the gold tinged apricot tiers of *P. Bulleyana*, but as a plant it is not too attractive. Save that it flowers a little later, it might be just a colour form of *P. japonica*. The still later flowering *P. Beesiana*, with flowers of some crimson hue with a varying admixture

umbels of flowers of bluish white or palest lavender.

Of the orange-vermilion *Primula Cockburniana* little need be said, since it does not like super-saturated soil and is only a biennial. It is mentioned here because it crosses readily with *P. pulverulenta*, and the resultant hybrids in varying shades of terra-cotta-red breed approximately true. The first crosses were called respectively Lissadell Hybrid and Unique, according to the pollen parent. Lissadell is a little freer flowering; Unique a little larger in the individual pip and a thought the better colour. Various slight differences of shade have now been selected and sent out under fancy names, but anyone who

has the two species can easily make the cross and raise numbers of plants himself.

It is difficult, if not impossible, to cross *P. Cockburniana* with *P. Bulleyana*, for instance; but if the attempt is made (*Cockburniana* being the seed parent) and seeds are obtained the majority will be typical *Cockburniana*, but a few will almost certainly resemble *Cockburniana* as to colour, though perhaps a trifle richer in tint, but will be more vigorous in appearance and growth, will throw far fewer, but much stouter, spikes and considerably finer flowers and be more truly perennial in character. No one, it is to be feared, has so far succeeded in perpetuating this fine form.

There will not be wanting critics to ask the reason for an article on these *Primulas* at this

season. Read, then, and perpend! If plants be procured now and placed in a cold frame or cool greenhouse and repotted if necessary, it should be possible, with the aid of a camel-hair brush, to obtain from a very few plants quantities of excellent seed which, if sown immediately it is ripe, will germinate like Mustard and produce numbers of plants to give a fine display for next season. Seed may, of course, be obtained from plants in the open, but it is easier to make sure of satisfactory pollination under cover.

None of these water-loving *Primulas* really needs the presence of water or even of bogland. All will flourish in cool, well cultivated soil on the shady side of a shrubbery, though they may, even there, require watering in an exceptional summer such as we experienced last year.

PRUNING BEDDING ROSES

No pruning will correct indiscriminating Rose planting. Each variety has its characteristic habit which may not be overcome.

UNDOUBTEDLY the best instructions for pruning Rose trees are those contained in the "Select List of Roses," issued each year by the National Rose Society. It would not, in any case, be possible in the course of an article in a gardening journal to give pruning instructions for each variety of any importance as is done in the book mentioned. Not that the instructions there given are perfect or complete, but they represent the best so far attained in this direction in an imperfect world.

Not all readers of THE GARDEN are, in any case, members of the N.R.S. Those who are will kindly, from the height of their superiority, forgive the elementary directions which follow, even though, as may happen, they find no new suggestions.

The time has now come when Hybrid Perpetuals and, in the Southern Counties, Hybrid Teas, may be pruned. A great deal of the bad pruning which one meets is due to ill-thought-out planting. Selection only by colour and quality and quite regardless of habit will place a bed of Hugh Dickson, for instance, between *Mme. Ravary* and *Ophelia*. To prune Hugh Dickson as it should be pruned gives a most uneven immediate effect and this unevenness is accentuated throughout the season. Hugh Dickson is a robust and excellent Rose, but it is not suitable for bedding and the same remark applies to many other strong growers. Frau Karl Druschki comes to mind as a flagrant instance of a Rose quite unsuitable for bedding in association with other varieties, and it is very doubtful whether even that old favourite *Caroline Testout* is not too tall for the purpose, as well as the salmon pink *Joseph Hill*. Neither of these varieties lend themselves to pegging down—a course which may be adopted with the Hybrid Perpetuals.

Now as regards the actual pruning of bedding Roses which, if well selected, will almost certainly, with the possible exception of *Lady Hillingdon*, belong to the Hybrid Tea and *Pernetiana* sections. All dead and unripe wood should first be removed. This latter will very probably be the thickest wood in the tree, being strong wood thrown up from the base late in the season. It corresponds roughly with what in fruit trees are called "water-sprouts." Any unduly thin wood had better be removed at the same time. The careful pruner will now take a survey of the tree before he commences to prune, since in bedding Roses the shapeliness of the tree is an important consideration. Having selected six or eight shoots (if there are so many), which are quite sound and healthy and which leave the

centre of the tree a little open, they should be cut back to from four to eight eyes of the base from which they started, always bearing in mind that the weaker the tree, the harder it should be pruned.

Some varieties are shorter lived than others. Moreover, really good Rose soils make for longevity. The bulk of Rose growers, however, have anything but ideal Rose soils, so that they must expect to have a good deal of re-planting to do. When the growths of a tree become more and more spindly the only remedy is replacement. Many gardeners always keep a few plants of each variety in the Rose garden by them in pots to fill inevitable gaps at pruning time or later.

The *Pernetiana* varieties are invaluable owing to their colouring, but it is wise not to employ them for bedding more than is necessary as they rather resent hard pruning and under bedding conditions are not long-lived. Perhaps the newer sorts will not suffer in this way as much as did those first introduced, but even the universally and deservedly popular *Mrs. Wemyss Quin* is not free from this defect. It is far stronger and happier when allowed to develop into a large bush. The following recognised bedding varieties call for hard pruning—to say four or six eyes from the base of the shoots—*Augustus Hartmann*, *Château de Clos Vougeot*, *Geo. C. Waud*, *Mrs. A. E. Coxhead*, *Mrs. C. Russell* and *Richmond*.

Where there are two rows of beds on each side of the garden or an extra row at the end or ends, it may be possible to utilise taller growing sorts on which a foot of growth may be allowed on new bottom wood and four or five eyes may be left on any laterals upon two year wood retained. Varieties suitable for this purpose and treatment are *Caroline Testout*, *Commandant Felix Faure* (H.P.), *Donald McDonald*, *Frau Karl Druschki* (H.P.), *G. Nabonnand* (T.), *Hugh Dickson* (H.P.), *Joseph Hill*, *La Tosca* and *W. C. Clark*.

The pruning of the dwarf *Polyanthas*, so popular now for bedding, is for this purpose very similar to the H.T. and T. sections, except that, as they are thin growers, more shoots may be retained and these cut over quite close—within two or three eyes of the base. This will give the dwarf effect generally worked for. If there is no desire to keep them down, little pruning need be done other than the removal of the spent (and eyeless) last season's bloom trusses. This pruning may now be proceeded with.

Since some folk like pegged-down Roses, it may be well, though the writer admits that he has no admiration for them, to explain the process, which certainly goes far to obtain new wood from the

bottom, which, incidentally, where pegged and naturally grown Roses are associated together, always forms a young forest, far taller than the vegetation in the other beds. For pegging-down then, all old wood should be cut away and the one year shoots left almost full length, right up to where the wood thins seriously or to where the buds have broken excessively, should this be lower than the thin wood. Tarred string is used for securing the growths to the notched pegs, which should be long enough when driven in to hold securely. About a foot is the usual length, but much depends upon the character of the soil. In some soil gin, pegs hold securely, in others it is almost impossible to persuade a peg to hold. Tie the string to the peg first and arch the shoot over to meet. If any attempt is made to lay the shoot along the ground it will snap off at the base. Some varieties, however, are much less brittle than others. Undoubtedly pegged Rose trees produce the greatest possible crop per plant, but the effect is, in the writer's judgment, much inferior to that obtained from beds of suitable varieties pruned in the usual way.

MIGNONETTE

"Here blossom red Roses, dewy wet,
And beds of fragrant Mignonette."

"Thistles and Roses."—ELAINE GOODALE.

THERE is the germ of a very attractive idea that I have several times seen carried into practical effect by sowing the ground between bush Roses with this old-fashioned fragrant annual. It is not a new idea by any means, but never, I think, have I seen a happier demonstration of the copartnership than in an old garden where a winding path meandered aimlessly along, with a narrow turf verge and a broad border on either side. These borders were filled with hundreds of choice Rose bushes: the time was July and the air a-quiver with blended perfume, in which the fragrance of the Rose and that of the *Mignonette* fought for ascendancy. One could not quarrel with the path for its lack of directness; indeed, the feeling was rather one of gratitude that one was permitted to linger a little longer in a neighbourhood so enchanting. One sometimes hears the plaint that *Mignonette* will not grow in this or that garden. The failure is due, in most cases, to the lack of knowledge of the would-be grower. Give the soil a good dressing of lime and the plant will grow and flourish as readily as Chickweed. Another way in which this grand old hardy annual is often very badly treated is as regards breathing space. Where only one seed falls and the plant can grow unhampered by the competition of its neighbours, it soon reveals the characteristic branching habit and spreads into a great plant, 2ft. or more across, and covered with dozens and dozens of the fragrant spikes. Dressed by nature in dull and unobtrusive colours, the plant is at no loss to advertise its presence, for, strolling in the garden after dark, one is made aware of its proximity by the all-pervading perfume that seems stronger than even at noonday. Delightful for cutting, it is, too, a favourite flower for draping the front of the window-box, and a room so furnished is always supplied with the distinctive and subtle perfume so charged with old association. Dry banks, old walls, gravel paths, between the interstices of a paved yard, anywhere, in fact, where the roots can find a hold upon a little soil and moisture, there is a potential home for the *Mignonette*; indeed, it often does better in such unlooked-for spots than in the rich, well-manured border. When sending

in an order for seeds one should not simply specify "Mignonette," for there is quite a large number of varieties, varying in colour and quality of fragrance. Covent Garden Favorite is a good one for fragrance, while there are also red, gold, orange and white sorts—this colour description

applying to the tips at the centre of the flower. Let the seeds be sown as though they cost 3d. each and there will be Mignonette in plenty of a size and quality never previously enjoyed where the plants have hitherto been given 6ins. of space in which to develop. H. W. CANNING-WRIGHT.

GARDEN ECONOMIES

Hardy flowers for summer bedding.

THERE is undoubtedly a widespread desire to reduce working costs in the garden. Old customs and conventions are, on every side, being crushed out of existence by excessive maintenance

charges. That there are many ways of economising applicable to gardens of all sizes without detracting from the general tone is not in doubt. Many of these have been exploited during the last few years, but more will follow. In regard to paid labour, it is rather difficult to draw the line at economy in working, as there is no room in a garden for a man without interest; and with many tasks, speeding up is at the expense of efficiency. Any saving where plant growing is concerned must be by way of dispensing with the superfluous. Economy with regard to bedding out has been engaging the writer's attention for some time. Where there is a large number of beds and borders to be furnished twice yearly, the work amounts to one of the most expensive in flower garden management. It is not, however, autumn planting that is costly, as the plants generally made use of are all raised in the open during the summer. It is the replacing of them in June where the need for economy is most felt, and where saving is possible. Those familiar with the raising of half-hardy plants for summer bedding out need no reminding that August finds them propagating numerous things which must remain on their hands for nine months, to the exclusion very often of more serviceable plants under glass. The cost of all this is greatly in excess of the results half-hardy plants can give, and in many cases is only allowed to continue in the absence of any practicable alternative method of hilling the beds. Roses have done much to lighten the working costs of the flower garden, but unfortunately their use entails a denial, on the ground they occupy of spring flowers, which is not desirable everywhere. Annuals provide another way of escape from wintering bedding plants, and the general effect is on a par with a scheme in which sub-tropical plants—

Geraniums, Lobelia, etc.—form the basis. It is rather surprising that Dahlias are not made more use of in the larger beds. The Mignon type grows about 15ins. high and leaves little to be desired. Even the taller forms have their uses,

SUCCESSIONAL SUMMER EFFECT IN A NARROW BORDER.
Gladioli amongst the golden yellow glaucous foliaged hardy *Tropæolum polyphyllum*.

Hardy plants have, however, proved to be the most labour saving of any, and the results have been satisfactory, as, when properly managed, the spring bedding display is not interfered with. Discretion in the selection of those kinds which best withstand transplanting is the secret of the whole system. The method is as follows: The month of May finds spring-blooming plants past their best before it has run its course. In the first week the hardy plants intended to follow are prepared for lifting by going round the roots at a convenient distance from the centre with a spade, and the ball is just loosened. This enables transplanting to be done with the least possible check. Once the beds are cleared, the soil is improved by

being liberally manured and deeply dug. The selected plants are then put in position, after being carefully lifted from their quarters with as much soil as possible adhering to the roots. In very dry weather it is advisable to fill the holes first with water. In any case a moist soil and firm planting is essential. When the time arrives for planting the spring bedding, the perennials are dug up and planted in a reserve plot for the winter. Some varieties may be a little impatient of removal the first year, but frequent transplanting encourages more fibrous roots, and afterwards they show little, if any, signs of distress. Of course, in many instances it is possible to plant bulbs, Wallflowers, etc., without removing the hardy plants, but this is a matter for individual taste. The system is eminently practical. It makes for no congestion under glass, and no trouble or expense all winter. As for the general effect, all depends on the plants made use of and the surroundings. In a series of strictly formal beds one might well utilise spring-sown *Antirrhinum* and annuals, reserving the larger ones for hardy perennials. As to these, it is some encouragement to know that one need not pass over many because of their early flowering, since most of the otherwise suitable kinds do not attain full beauty until midsummer or after *Pyrethrum* and *Doronicum* are the principal free-flowering exceptions. Nor is their use altogether impossible, as both form an excellent groundwork for *Gladioli* or *Cape Hyacinths*. A bed of this description is not surpassed by any combination of half-hardy plants. Others which will suggest themselves to those familiar with their habits include the *Geums*, especially the newer sorts, which are an improvement on the now famous *Mrs. Bradshaw*; *Gaillardias* and *Coreopsis*, associated with the scarlet-flowered *Lycnis chalcedonica*; *Artemisia lactifolia*, amid a setting of *Pentstemon* forms a novel but attractive picture. For Herbaceous *Phloxes* no praise is too high, and though *Delphiniums* are dwarfed by constant transplanting, the effect of good varieties is always pleasing. *Erigerons*, *Nepeta Mussini*, *Violas*, the dwarfier forms of *Helenium*, together with *Michaelmas Daisies* and Hardy *Chrysanthemums* by no means exhaust the list of hardy plants which may be employed with remarkable saving of labour. J. T.

THE IMPORTANCE OF THE SEED-BED

"Too much haste, no speed," applies, with great force, to seed-bed preparation.

THIS is a vital operation, upon which everything connected with the well-being of a plant depends. It matters not whether the seeds be of good germinating power or the stock of the very best strain; whether the plants receive the best of attention or are given the choicest site in the garden—if the seed-bed is not of the best construction, everything fails, because the plant is crippled and ruined from the very start, and a crippled plant is not the one that is going to afford the results desired of it. Many gardeners blame the seed, others the weather, the soil itself, insect pests, disease and other things, but it is very often the badly made seed-bed that militates against success.

In making up a seed-bed four things should be considered—site, soil, drainage and weeds—each of which has a remarkable bearing upon the success or non-success of the seed-sowing operation.

First the site. It *must* be an open one to start with; an overshadowed site is usually sunless,

cold, damp and insect infested. The neighbourhood of trees and shrubs should be avoided; but more injurious, perhaps, is the presence of lower-growing spreading plants, such as perennial flowers. One of the best of sites is a row across the allotment or vegetable garden. This applies to flower seeds as well as those of vegetables.

Beyond question the soil should be deeply dug and deeply manured, which makes for fertility and also for efficient drainage. Drainage should be attended to while treating the soil. Deep digging will often accomplish this, but it is best to put a few inches of brick rubbish or stones into the bottom, if possible. However that may be, the soil should be of the right sort. If it is stiff, clayey, or full of stones, it must be lightened by the addition of other materials, such as sand, road-grit, leaves, etc., and the stones removed. If it is of a sour nature it must be sweetened by the application of lime. If of light texture, some loamy, leafy soil should be incorporated with well rotted manure; this so far as the bulk of the soil is concerned. It is necessary also to have a fairly fine surface

on which to sow the seeds; and it will not be wasteful if a barrowload of a good made-up compost—loam, leaf-soil and sand—is spread over the existing surface to the depth of tin, or zins., for this will give the young seedlings that congenial rooting medium which the fine, delicate rootlets need so much.

A good start often guarantees a good finish, and a plant which thus finds itself born into a world that caters perfectly for its needs from the very starting point of existence will be enabled to gather the necessary strength to carry it through the succeeding stages of its life. A suitably prepared soil does this as nothing else can do.

Lastly, there are weeds to deal with; and weeds so often mean ruin to seedling plants. From the first, then, weeds should be vigorously fought against and rooted up, even if it means sacrificing some of the seedlings as well. (Plants never lose anything by being thinned, at all events!). After each successive weeding a very gentle syringing will settle the good plants into the soil again.

H. A. DAY.

EARLY-FLOWERING CHRYSANTHEMUMS FOR BEDS AND BORDERS

FEW plants that flower outdoors in late summer and throughout the autumn compare, for beauty and usefulness, with the Early-flowering Chrysanthemum.

This type of the Chrysanthemum is not cultivated for the production of large blooms of high quality for exhibition, but is exclusively grown to make a bright and pleasing display outdoors or to provide cut flowers for all forms of the floral decorator's art. Although the newer forms of the early-flowering outdoor Chrysanthemum are represented in many charming shades, they will not compare in regard to colour with the gorgeous hues of the more brilliant Dahlia; but then these Chrysanthemums are of hardier race than the Dahlia, and the Chrysanthemum blossom has a beauty peculiarly its own. The Dahlia flowers with the greatest persistency and one may cut and come again, day after day, without materially interfering with the general effect of the display outdoors, but the blooms do not long maintain their freshness. On the other hand, the Early-flowering Chrysanthemum gives but one crop of blossoms, and these in beautiful sprays that last for several weeks, and in a cut state for a considerable time. Often, too, these plants continue to make a display for a considerable period, if care in the selection of sorts be observed, so that by beginning with the earliest, continuing with the second early and completing the display by the inclusion in the selection of a number of varieties that come into flower in mid-October, it is possible, unless the weather be very unpropitious, to have Chrysanthemums in flower outdoors from late August until November. I have frequently seen Dahlias blackened by frosts while the Chrysanthemums have made the beds and borders bright with their profuse display, as they stand several more degrees of frost than does the more brilliant Dahlia.

Progress in the development of the Early-flowering Chrysanthemum has been very slow in recent years, and this, to the writer, is a matter of sincere regret. Twenty-five to thirty years ago, through the industry of a well known French raiser, M. Simon Delaux, an impetus was given to the cultivation of these plants, and for a few years subsequently thereto, with an occasional introduction from the European Continent and the efforts of one or two English raisers, a really

satisfactory collection was got together. Little appears to have been done in more recent years, however, to add to the list new and improved varieties: we seem now to be marking time. Strange to relate some of the more noteworthy sorts for border culture in general cultivation to-day are those distributed by M. Simon Delaux about thirty years ago. Mme. Marie Massé, a well known lilac-mauve sort, for which variety the writer was awarded the first-class certificate by the National Chrysanthemum Society's Floral Committee on October 8, 1895, was the forerunner of many excellent additions to the early kinds. The flowers of this variety were exhibited on September 25, but as no award could be made unless a plant was submitted to the Committee, this was forthcoming at the next meeting—October 8—when the award was confirmed. These facts are interesting in view of what happened subsequently; for Mme. Marie Massé produced sports, either directly or indirectly, of which the following record is worth noting: Ralph Curtis, creamy white; Rabbie Burns, rosy crise; Horace Martin, bright yellow; Crimson Marie Massé, chestnut crimson, passing to bronze; Ethel, primrose; Geo. Bowness, crushed strawberry (raiser's description); and Wells' Massé, white, slightly shaded blush. There are, therefore, at least eight sorts that have all sprung from the same stock, and I believe plants of all the eight sorts can be obtained from the leading specialists to-day. I give prominence to the foregoing family, as I have always regarded and still adhere to the view that plants of Mme. Marie Massé and its sports represent what is ideal in Early-flowering Chrysanthemums for border culture. The plants are profuse bloomers, possess a splendid branching habit of growth and enjoy a constitution that is truly perennial. You cannot kill the plants by the roughest treatment. Pieces may be broken out from the old crowns in the spring from which excellent plants may be made, or they may be divided up into numerous pieces, each with a few shoots. In the flowering season handsome sprays of blossoms are evolved, and each flower in the sprays has a useful length of foot-stalk. This set of plants does not take kindly to disbudding, and for this reason they should be grown quite naturally. The plants attain a height of from 2½ft. to 3ft., and they begin to

flower from early September and continue in flower, more or less, for fully two months. What more could one expect of a Chrysanthemum?

Other sorts which may be placed in the Japanese section, and which should receive consideration, are the following: Goacher's Crimson, large rich crimson, in flower during September and October, 2½ft.; Almirante, chestnut crimson, beautifully branching, September and October, 2½ft., should be in all collections; Howard H. Crane, bright chestnut, October (late), 3ft.; Leslie, buttercup - yellow, late August and September, 2ft.; Cranford Yellow, rich bright yellow, October, 3ft., partially disbud this variety; and Martin Reed, a beautiful golden yellow sport from Perle Chatillonnaise, late September and early October, 4ft.

Chaste white sorts should be represented by Roi des Blancs, a rather spare plant that produces the daintiest sprays of pure white blossoms in late August and September, 3ft.; Sanctity, also known as Candida and Excelsior, a large flower of the purest white, should be partially disbudded, September and October, 2ft.; and Framfield Early White, purest white (partially disbud), September and early October, 3ft.

Bronzes and terra-cotta shades are seen in excellent form in such sorts as Nina Blick, orange scarlet, passing to golden bronze, must be partially disbudded, sturdy grower, September and early October, 2½ft.; Polly, bronzy yellow, rather spare grower, September, 2½ft.; J. Bannister, lemon, shaded copper, late September and October, 4ft.; and Dolores, bronzy terra-cotta, early October, 3ft.

Pink, rose and kindred tones of colour are seen to advantage in Normandie, delicate pink, early September, 2½ft.; Cranford Pink, soft pink, must be partially disbudded, otherwise it is uninteresting, October, 3ft.; Improved Massé, bright rose, early September, 2½ft.; Mrs. Marshall Field, shell pink, end of September and October, 2½ft.; and Pride of Hayes, deep rose, October, 3ft.

Varieties of nondescript colour worthy of a place in the garden include the following: Dick Barnes, rich burgundy crimson, September, 2ft. Perle Chatillonnaise, cream, tinted blush pink, late September and October, 4ft.; El Draco, orange amber, October, 2½ft.; Chatillon, salmon and gold, very free, early September, 2½ft.; Mme. Casimir Perrier, creamy white, tinted pink, very free, September, 2½ft.; and Roi des Précoces, a distinct tone of velvety crimson, late October, 2½ft.

A few good sorts for growing in disbudded form—i.e., one bud to each shoot—should include Cranfordia, old gold, broad florets, October; Sanctity, purest white; Pink Delight, bright pink, early October, 3ft.; Southover Yellow (sport from Framfield Early White); Ena Thorpe, shell pink, incurving petals, September, 2½ft.; and Mrs. R. Hamilton, deep golden yellow, October, 3ft.

A few single-flowered sorts may appeal to some readers. They are Merstham Glory, crimson; Mrs. C. H. Curtis, velvety crimson; Brazier's Beauty, blush; Florence Gillham, white; Shrapnel, orange terra-cotta; and John Woolman, pink with white zone round disc.

The foregoing varieties should meet the requirements of those who desire to make a bright and beautiful display throughout the autumn. Over-rich soil for these plants is apt to produce an undue amount of growth at the expense of the flowers. For this reason Chrysanthemums should be planted in soil of only moderate richness. If not already dug over, the sooner this is done the better, as this will leave ample time for the weather to sweeten and pulverise the quarters it is desired to plant. In large borders three plants of a sort

should make a beautiful splash of colour, and where pleasing contrasts are wanted it should be an easy matter to achieve these results with only elementary knowledge of the capabilities of these plants. Plant the Mme. Marie Massé family 3ft. apart, and most others about 2½ft. asunder, and then the intervening spaces should be filled up before the season is over.

Order plants from the Chrysanthemum specialists at once, and as these are usually very small, they will need careful handling for a time. The most satisfactory method, in my experience in dealing

with these little plants, is to plant them out about 4ins. asunder in rows in a cold frame, in any light gritty compost, planting rather firmly. Water in lightly, using a fine-rosed can; keep the frame close for a few days, and as the plants become established, admit air, increasing this as time progresses and the plants make headway. Ultimately remove the frame-lights altogether. Plant outdoors in the early days of May, when danger of cutting winds and frosts is reduced to a minimum. The plants may then be lifted with a mass of roots.

D. B. CRANE

FORCED BULBS AND HARDY FLOWERS AT VINCENT SQUARE

THOSE who, on entering the R.H.S. Hall on the occasion of the mid-March fortnightly meeting turned to the right, might well have felt that it was "Hyacinth Day," for this spring bulb decidedly predominated. Messrs. Sutton and Sons had a large collection of some of the finest pikes

buy goodly bunches of flowers in the streets for a few coppers.

Next to the Hyacinths and other spring bulbs it was the many little colonies of Saxifrages that attracted attention. In the exhibit by Mr. C. Elliott there were a few tiny plants of *S. Mira*, each bearing just one pink bud or open flower.

VERY SUBSTANTIAL AND BEAUTIFUL.

THE NEW NARCISSUS WHITE OWL.

we have seen and their arrangement was distinctly tasteful. Of the numerous varieties the best grown was the yellow City of Haarlem, though the Dresden china blue of Schotel was very fascinating. Chestnut Flower is an uncommon colour in Hyacinths, and is well described by the name.

In the large exhibit by Messrs. R. and G. Cuthbert there were fine spikes of Menelik, the darkest of all dark blues.

That excellent Hyacinths, Narcissi and Tulips can be grown in bowls of fibre was fully evident by the collection of Messrs. R. H. Bath, Limited, and here many visitors were charmed by the bowls of *Fritillaria Meleagris*, which certainly were decidedly elegant and fascinating. These quaint bulbs are quite good room flowers either when growing in bowls or as cut-flowers. In the meadows along the upper reaches of the Thames they grow in great profusion, and most years the people of Reading and other riverside places are able to

This is one of the late Mr. Farrer's plants and in colour is a great advance on *S. Irvingii*, which was freely shown in great beauty. One little group of alpine plant enthusiasts discussed the quaintly attractive *Saxifraga Greisbachii* Wisley variety, which far surpasses the type. At first it was voted most beautiful, but finally, after much good-natured banter, it was agreed that quaintly attractive was more appropriate for the tuft of silvery foliage and the hairy crimson bracts on the flower stems. *S. lilacina* really is a delicately beautiful flower.

The most noteworthy representatives of the Iris family, which at earlier meetings have been numerous, were the several excellent pots of *Iris fumosa*, one of the best of the April flowering section. It bears quite large violet flowers of delicious fragrance.

Chief among the flowering trees and shrubs must be placed the remarkable group of pot

Camellias by Mr. William Paul. These were all clean, healthy specimens and exceedingly well flowered. It is the single-flowered varieties that are most successful in the open, and among those present were Lady McKinnon, Mrs. J. Buchanan, Adelina Patti, Vesta, The Swan and Jupiter. Azaleas of the various types were plentiful, and the most attractive were *A. Hidomanyo*, a charming soft salmon pink little bush of *A. Kämpferi* and *J. C. van Tol*, a *mollis-sinensis* hybrid which is nearer the *mollis* section in size and habit. It becomes a glowing bush of brick-red colour with a sheen of orange salmon.

The Narcissus season may be said to have fairly commenced, as there were several very good collections on view. Many of the newest sorts were as yet unnamed, but they were very promising, particularly those belonging to the large trumpet section. Goldbeater is a rich yellow self of large size and fine shape. Darius is a bicolor with a canary yellow tube rising from a primrose perianth. Vestal Virgin, another of the large trumpets, is paper white and a sulphur yellow tube. Perhaps the largest of all trumpets was Mrs. H. J. Veitch, though the quantities of King Alfred in Messrs. Carter's graceful exhibit were splendid.

NEW AND RARE PLANTS.

***Pieris taiwanensis*.**—The name suggests that this is one of Wilson's Chinese discoveries. It is a wonderfully good shrub and, if it proves to be hardy, will be a decided acquisition. It is nearest to *Pieris (Andromeda) japonica*, but bears a more erect spike of whiter, rounder and rather larger flowers. The leaves are much broader than those of *P. japonica*. The plant on view suggests that this species flowers when quite young. Award of merit to the Marquess of Headfort.

***Freesia Wistaria*.**—Although the coloured *Freesias* are now becoming somewhat common and include many distinct shades, there is none quite like this one. The three inner petals have the same blue-mauve colour as *Wistaria sinensis* flowers, while the outer petals are simply flushed with it. The spike and blooms are both good, but, unfortunately, there seems to be no fragrance. Award of merit to Mr. G. H. Dalrymple.

Narcissus White Dame is a large trumpet Daffodil of perfect form but rather thin in texture. The frilled trumpet is widely open and has a reflexed rim. The colour is that known as paper white. Award of merit as an exhibition variety to Mr. G. L. Wilson.

***Narcissus White Owl*.**—This might almost be termed a *Polyanthus-Leedsii-Tazetta* Daffodil, for it bears twin *Leedsii* blooms on a *Tazetta* growth. It was raised from Minnie Hume and Scilly White. In general appearance the flowers are like small *bilora* trumpet blooms; they have plenty of substance. The round sepals are white and the trumpet is pleasingly shaded primrose. An excellent variety for pot cultivation. Shown by Mr. W. F. M. Copeland.

***Violet Tina Whitaker*.**—This is a large flowered single variety which has somewhat the appearance of a poor *Viola*. The long petals are thin and pointed and the colour is purplish. Shown by Mr. H. A. Perkins.

***Odontioda Opal*.**—A very fine spike of roundish flowers which have dull crimson markings edged with lilac and white. The white lip bears a rich yellow crest. First-class certificate to Messrs. Armstrong and Brown.

***Sophro-Laelio-Cattleya Falcon Westonbird variety*.**—The flower is so dazzlingly beautiful that one can forgive its cumbersome name, for which, after all, it is in no way responsible. The blooms are as nearly perfect in form as possible. The ground colour is a vivid, sparkling cardinal red, and this has a sheen of fiery orange. There is a

velvety crimson lip and an orange throat. First-class certificate to Sir George Holford.

Cymbidium Alexanderi Westonbirt variety.—This is the most perfectly formed Cymbidium imaginable and a very beautiful flower withal. The robust, erect spike bore half a dozen roundish fleshy blooms having pearly white segments and a

crimson splashing. Award of merit to Sir George Holford.

Sophr-Cattleya Prince Shimadzu.—A very beautiful flower in which the segments are heavily mottled with rose in an uncommon fashion. The broad, golden lip is deeply margined with rose pink. Award of merit to Messrs. Flory and Black.

A MAGNIFICENT LILY-OF-THE-VALLEY SHRUB—PIERIS TAIWANENSIS.

lip evenly spotted with rosy crimson in the centre of which are the two yellow ridges. First-class certificate to Lieutenant-Colonel Sir George Holford.

Cymbidium Alexanderi variety Rosalind.—Although not of such perfect form as the above, it is a very charming flower. The ivory white segments are delicately flushed with pink and there is a rose pink edging to the lip shading to

Apple Peter Lock.—This seems to be a good late general utility fruit, for it is recommended both as a dessert and a culinary variety. It is a large, round, flattish fruit somewhat like a very golden Wellington. The sunny side is lightly striped with crimson. It is said to be quite common in the orchards in the neighbourhood of Buckfastleigh, Devon. Award of merit to Mr. J. A. Devenish, Goulds, Staverton, Devon.

SPRAYING IN SPRINGTIME

Fruit trees which were not sprayed in winter should be sprayed in spring. Those sprayed then may need spraying again.

THE relative value of winter spraying and spring spraying has been the subject of much discussion. Indeed, it is almost as debatable a point with the advocates of spraying as has been the practical value of spraying itself between its disciples and those who will have none of it.

Whatever may be the value of winter spraying—and for some purposes it is the best thing we know—it is too late now to benefit our trees by dwelling upon the matter, but if winter spraying was neglected, it is imperative that careful attention should be given to spring spraying, and even where the winter spraying was carefully and thoroughly done, there may very likely be need to spray again in spring. If trees are known to be troubled by only one pest or disease, and its identity is established, it may be comparatively easy to decide whether the one season or both will be involved in the measures to be adopted to grapple with the trouble. The unfortunate point is that a predisposing cause of attack is impaired health of the tree, and as soon as such condition affords

opportunity, not one but several pests and perhaps, fungoid diseases as well, fall upon the tree to work their havoc. Another thing is that the injury worked by one enemy renders the tree vulnerable to attack by another, and therefore even if we may have destroyed a host by winter spraying, it may be just as necessary to ward off quite a different host by spraying again in spring.

The fluids that may be used during the winter when the trees are leafless and dormant are more caustic and penetrating than can be used with safety when the buds are bursting into new growth. On the other hand many comparatively mild and simple washes will prove thoroughly effective if used just at the right time.

The right time is governed by natural causes, which regulate the awakening of activity after the winter's rest. If we have warm sunshine and absence of frost during the latter half of March our trees break early, and the ova of insects will hatch. If, on the other hand, we have a continuance of sunless days and cold nights the renewal of activity will be delayed. Instead, therefore, of

fixing up a spraying calendar, it is wiser to work from a chart that takes the stage of development into first consideration.

For instance, we may suppose our trees were affected last year by attacks of the grubs of one or other of the winter moths, the codlin moth, or the psylla (Apple sucker). The date of hatching of the larvæ of these pests will closely coincide with the bursting of the buds. We want to give them a poisonous breakfast, and that must be given before they can bury themselves in the core of the embryo fruit. We cannot, however, spray when the trees are in full bloom, for that would endanger the pollen. The best plan therefore is to spray just before the first buds break, and then, to make perfectly certain, spray again when the petals have fallen. It would obviously be foolish to work such a task by date. The situation of an orchard or garden, combined with the vagaries of our climate must render any fixing of dates abortive. Furthermore, even in one garden or plantation some varieties will come into bloom earlier than others, and every tree should be watched and treated individually. This means trouble and irksome labour, but it spells the difference between success and failure, and it is worth while taking the trouble to rid trees of the pests that can destroy the crops.

Talking to an enthusiastic cultivator recently, who is famous throughout his district for securing consistently good crops even when neighbouring growers have failed, he assured me that for over a dozen years he has made a practice of using a knapsack for half an hour to an hour a day spraying his trees just as they individually reached the stage of showing the first signs of bursting. He would as readily think of giving up spraying altogether as attempt to make one complete job of all his trees at one operation. There lies a fundamental point, and it is worth taking a deal of trouble to ascertain just when to spray.

For the pests aforementioned arsenate of lead wash makes a reliable and effective spray. It is a poisonous compound, and although it may be prepared by dissolving arsenate of soda with acetate of lead in water and adding treacle to make it adhesive, it is safer to buy a properly prepared paste and dilute according to directions given on the canister.

Lime-sulphur is another useful spray for spring use, its purpose being to arrest the development of many fungoid diseases. It is also a capital spray to use as a deterrent to birds that are wont to pick at the swelling buds. It is possible to combine these two mixtures, making one spray serve the dual purpose of insecticide and fungicide, but they must be blended with care else the one will destroy the power of the other. It is a chemist's job rather than an amateur's.

Before long we shall require to be on the track of the first batches of aphides that will be hatching from eggs that have lain dormant during the winter. A very effective spray, so long as it is thoroughly well emulsified and kept agitated throughout the process of spraying, may be made by bringing half a pound of good soft soap to boiling point in a gallon of water, then adding two gallons of best paraffin oil, stirring with vigour until the whole is converted into a creamy emulsion. The solution will make 100 gallons of spray. The essential point is to keep the oil thoroughly mixed by repeated violent stirring, for if the paraffin is allowed to rise to the surface the spray will lose its effectiveness, and the oil will damage young foliage. A spraying machine with a paddle or agitator inside the tank will keep the fluid thoroughly emulsified.

The value of nicotine for destroying aphides and most gnawing and sucking insects is so great that even at the high prices at present prevailing we can ill afford to do without a good nicotine wash.

A. J. MACSELF.

CORRESPONDENCE

TRANSPLANTING TIMES.

WITH reference to your note (page 111 of THE GARDEN for March 11) that the May planting fetish is dying out, I have always understood, as an amateur gardener, that for Yews the end of April or the beginning of May was the time for transplanting *par excellence*. Should this not be so, it is very desirable that the fact should be given the widest possible publicity, and I do think that a discussion contributed to by those entitled to speak with authority not only on this point, but upon the best times for transplanting in general, would be of the greatest interest to gardeners.—L.

Our correspondent's suggestion is an excellent one. We shall gladly find space for a discussion of the question.—ED.

TREE LUPINS IN THE BORDER.

THE Lupin appears of late to have become exceedingly popular, which, considering comparatively recent improvements in colouring, is not to be wondered at. It seems now to be quite fashionable to plant strains which have been produced by crossing the shrubby so-called Tree Lupin with the herbaceous forms. The quiet, restful colourings of most of these crossbreds are very beautiful when a cut spray is examined, but few people use Lupins for cut-flower owing to their shedding propensities. Looked at as garden flowers these forms seem to me far inferior to either of their parents. The extensive range of colour now obtainable in the herbaceous forms contains many shades at once brilliant and pleasing—this even to the most captious—but it is of the value of the too neglected Tree Lupins that I feel impelled to write. Their only real failing is shortness of life, which is especially manifest in the North and East, where only young robust plants can be depended upon to withstand the rigours of winter. They are, however, readily and rapidly replaced from seed and need replacing no oftener than a well kept herbaceous border must be re-made, so that, personally, I have not found this an appreciable drawback. They are, when in blossom, among the most satisfying features of the garden, while merely as a foil to other plants and a harmonising influence they earn their place in the herbaceous border. Forms are now obtainable which are almost golden yellow in colour, but give me the old-fashioned creamy-white variety and more particularly the typical soft yellow!—MIDLANDER.

THE WYCH ELM AND OTHER MATTERS.

I SHARE with "Somers" (March 11, page 114) the feeling that trees are truly seen when leafless. A tree seen thus in winter, with the sun rising or setting behind it, always affords me

a peculiar pleasure, surpassing all summer joys in it. When he writes of a Wych Elm in particular he touches me closely, for we had one in our old Surbiton garden. It served as our outdoor summer sitting-room, and we children used its lowest branch as our "horizontal bar." "Somers'" description of its "domes" is perfect. Like him, too, I count all I see as mine, and am now part owner of a beautiful park, whose nominal owner wots not of my existence. He pays all the expenses and has all the worry of it—a truly admirable partnership from my point of view.

The neglected Begonias, with their ruddy foliage, as pot plants, I also found out a few years ago. They are—as "C. T.," Amptill, writes (page 120)—delightful. The Night-scented Stock is never absent from my "fragrant border," and at the present time (March 10) is coming up in self-sown masses under my west room window. I "carry off" its daytime shabbiness by planting some purple "Daytime" Stocks close against its clumps. I hazard the surmise that it opens at night to be fertilised by some special moth possibly?

I am so pleased to see "Clarence P.," again in THE GARDEN; his humorous and practical paragraphs have too long been absent. I agree with his objection to the "ii" termination—

THE VALUABLE TREE LUPIN—LUPINUS ARBOREUS

Jonesii, Smithii, Brownii, Greenii, Blackii, and the rest. I wish Mr. Allwood would make a new departure with his new plants and call them Allwood's Dianthus. By the way, Clarence, you are not the only sufferer from parental cruelty, in choice of your Christian name! Mr. Allwood's is Montague, and mine are as many as a Royal princess's. Tumtidy Marianne Tumtidy Tiddy-tum Tumtidy. What a life the girls at the Ivy House Hackney High School led me! especially

as one of my names was that of the heroine of a popular poem—and girls were not allowed to fight *then!* Perhaps they are now. So many things have changed since I was young!—ANNE AMATEUR.

THE HARDINESS OF EUCALYPTUS GLOBULUS.

IN THE GARDEN of March 11, page 120, your correspondent, "J. P.," writing under the heading "Eucalypti," wonders "whether Eucalypti, Camellias and Mimosa could possibly, with protection, be induced to grow in the warmer parts of Cheshire." Without venturing an opinion on the exact point raised, it may be of interest to "J. P." and many others if I remind them that Osgood Mackenzie, Esq., has in his grounds at Inverewe, North-west Ross-shire, several specimens of Eucalyptus Globulus, which were several years ago of pit-prop size. Further, Sir Herbert Maxwell, in his delightful book, "Scottish Gardens," page 82, tells of a 30ft. specimen of E. Globulus, at Castle Kennedy, Wigtonshire, which was blown down by a gale in 1894, but which was again showing its hardiness there by means of a fresh stem thrown up from the root. Sir Herbert also tells of a 20ft. specimen of Acacia dealbata, which was killed by the severe frost which occurred on April 24, 1908, a date which came between his seeing it at Castle Kennedy and the publication of his book. The death of this Mimosa was attributed to the fact that it had made, immediately previous to its decease, unusually vigorous growth, owing to the warm weather at that early period of the year. As Sir Herbert in his introduction to his book points out, the relative hardiness of plants in Britain is not so much a question of North and South as of East and West.—CALEDONIA.

EFFECTS OF DROUGHT.

GARDENERS as a rule do not realise that the flowering period of nearly all annuals can be extended by cutting back the plants as soon as the first rush of bloom is over. During the late dry summer most people will have noticed how quickly annuals came into blossom and how soon that blossom faded. In this garden some large patches of blue Nemesis, double Godetia, Nicotiana, crimson Flax and others were cut over with shears as soon as the first flowering was over. After one or two waterings the plants started into growth again, and the second blossoming was as effective as the first and more lasting. Among perennial plants which enjoyed the heat and drought were the following: All Gypsophilas, Lavatera Olbia, all Eryngiums and Echinops Ritro, Helenium and Rudbeckias looked miserable and suffered far more than did Phloxes in this cool, heavy soil. The only plant actually killed by drought (except wall plants) was London Pride. In full sun this all perished. I have a good deal of old flint and brick wall in which various plants are naturalised. These are chiefly Pinks of several species and varieties, Erinus alpinus, Sedums and Sempervivums. All the Pinks were killed, including large old plants of casius and plumarius. D. deltoides was the first to go. Out of many hundreds of plants of Erinus not half a dozen are left. However, I fully expect that both these and the Dianthi will reappear from self-sown seed. Sedums and Houseleeks were unharmed and, strange to say, the damp-loving Arenaria balearica has survived here and there where shaded from the sun. Ivy-leaved Toadflax and yellow Corydalis still hold their own. None of the walls are "retaining" walls, and they are all built with mortar. When one considers that for months no moisture can

have penetrated the crevices and that the walls were baked through and through by the sun, it seems wonderful that any plants should have survived.—B. C. T., *Hants*.

A QUESTION OF CULTURE.

"A. E. W." says (March 11, page 112) that *Iris unguicularis* needs "very poor soil." It is true that this *Iris* may flower well at the foot of a south wall in the poorest soil, but the finest flowering clumps of it that I have ever seen were planted in a rich Vine border facing south, where the plants had also the benefit of being close to a wall warmed inside by hot-water pipes. Heat, not quality of soil, is the essential requisite for making them flower well.—H. ROLLO MEYER.

A LITTLE-SEEN ROCK PLANT.

SOME years ago I obtained a plant of *Calceolaria polyrhiza* which, with some misgivings, notwithstanding its supposed (or catalogued) hardness, I planted out in a sheltered corner of my little rock garden. There it has flourished greatly and increased rapidly by running underground, so that I have established pieces in other

THE TOO LITTLE-SEEN CALCEOLARIA POLYRHIZA.

and colder places, even between paving stones in another part of the garden altogether. I still occasionally find it listed in hardy plant catalogues, but I never seem to see it in gardens I visit unless it be a plant which originally was obtained from me. I think its want of popularity may probably be due to the fact that being a *Calceolaria* its hardness is mentally called in question and also to its catalogue descriptions, which seem to lay emphasis on its quaintness and quite overlook its real charm and beauty. Few plants can possibly be easier "doers" or more worth growing by those to whom beauty is not dependent on mere size.—E. N. Q.

FORTHCOMING EVENTS.

March 28—Royal Horticultural Society's Fortnightly Meeting (two days). Masters' Memorial Lecture, by Dr. Harold Wager, on "The Behaviour of Plants in Response to Light," at 3 p.m. on the first day.

March 29—Irish Gardeners' Association and Scotch Society's Meeting. Glasgow and West of Scotland Horticultural Society's Meeting at 7 p.m. Lecture on "Rock and Water Gardening."

April 1.—Paisley Florists' Society's Show

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cauliflowers.—It is an immense gain where arrangements can be made for an early batch to be grown under glass. This may be either in 8in or 9in pots or, better still, in deep pits facing south, having a flow and return water pipe system for use on cold evenings. The pits should be of sufficient depth to allow for a bed of leaves and litter. This bed should be prepared in time so that the heat is on the decline when the plants are placed in their final positions. After carefully hardening other batches they may now be planted out in well enriched soil and, if possible, in a warm, sheltered spot to come along quickly. A slight protection such as afforded by a few evergreen boughs should be given if cold winds are prevalent.

Beetroot.—On a warm well worked border a small first sowing may be made, choosing a Globe-rooted variety for preference. For this early crop allow a distance of a foot between the drills.

Dwarf French Beans.—Make use of as many frames as possible to maintain an unbroken supply of this vegetable, and as it is still too early, "except in the more favoured spots," to sow outside, sow some seed thinly in shallow boxes and place in cold frames. These will be ready to transplant to a warm border a little later.

Cucumbers.—Make a sowing at once, if not already done, to furnish plants suitable for use in frames or a succession batch inside. Plants growing and fruiting freely require constant attention in stopping and regulating the growths, while with lengthening days and stronger sunlight plenty of moisture will be needed both atmospherically and for the roots. Frequent top-dressings are of the utmost benefit to enable plants to carry a heavy crop of fruits, and a suitable compost would be fibrous loam, spent mushroom manure and some flaky leaf-soil.

The Flower Garden.

Planting and Pruning.—The present is a suitable and proper time for each of these operations in connexion with some of the occupants in and around the flower garden. With the exception of Hollies and Bamboos it would be well to get the planting of evergreens completed soon, especially on light soils, but with the two plants named there is no hurry for another three weeks; indeed Bamboos often "go away" more quickly if the planting is deferred until the early days of May. An important point in connexion with the planting or transplanting of shrubs and trees is to have everything in readiness so that the work may be carried out quickly and no unnecessary suffering be imposed upon the roots of the plants dealt with by long exposure to unfavourable climatic conditions. In dealing with the pruning of shrubs, especially flowering ones, I think the same remark applies as with Roses—an intelligent enthusiast will quickly see what his or her plants require as far as the knife is concerned. Where Ivy is used as a covering I think the end of March affords really the best time for hard pruning, as the genial and growing days oft experienced during April will soon induce new growth to hide the bare appearance following severe pruning.

Plants in Tubs, among which include *Hydrangeas*, *Lippia citriodora*, (Lemon-scented Verbena), *Fuchsias* and *Agapanthus*, should now be encouraged to grow freely giving such attention as necessary to top-dressing or retubbing. Where these plants are required at their best late in the season, much may be done towards arriving at this end by retarding them as long as possible at this season.

Fruit Under Glass.

Pot Strawberries.—Increased sun-heat and longer growing days will render it necessary to give these plants more attention, particularly those which were introduced into the houses some weeks ago. These are now full of activity in leafage and at the roots. Dryness at the root must be guarded against, and it is also necessary on all bright days to give the foliage of the plants a couple of good syringings, unless of course during the flowering period. More manure water may be safely used now on plants swelling up their fruits, but discontinue this when coloration sets in likewise the spraying of the plants, and endeavour if possible so to arrange that a goodly amount of air may circulate among the plants so that as good a flavour and finish may be given the fruits as possible. See that some support

is given the fruit either with sticks or by stretching a couple of strands of twine under them and looping it at intervals to permanent wires in the house or to some secure temporary arrangement.

H. TURNER.
(Gardener to the Duke of Northumberland.)
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Parsley.—A good breadth of this popular herb should now be sown. This first sowing thrives best if allotted a part of the early border where the soil has been deeply dug and well manured. Sow in shallow drills 12ins. apart. Run the hoe through between lines of old plants and so encourage enough growth to last until early sowings are ready for picking.

Seakale.—Plant the necessary number of sets now for providing strong crowns for forcing purposes next season. The sets that were prepared some time ago and laid in sand will now be showing several shoots at the top. Rub these off with the exception of two of the strongest. Draw shallow drills 18ins. apart and plant the sets 15ins. apart in the drills, covering the crowns with 1in. of soil. After growth is advanced rub off the weaker of the two shoots.

Spinach.—Make frequent sowings so that fresh pickings may be maintained. Sow also Spinach Beet, as this proves a valuable substitute should the summer variety fail through drought or other causes.

Globe Artichokes.—The rough litter which has been used as protecting material during the winter may now be removed and the ground forked between the plants, at the same time giving a liberal dressing of well decayed farmyard manure. Should new plantations be necessary, the work may be carried out at this time. Where the soil is stiff and clayey work in a quantity of leaf-soil, lime rubble and cinders. This will be found helpful in freeing the soil and encouraging root action.

Leeks.—Seed should now be sown in the open border. This sowing will, in most gardens, provide the principal planting of this indispensable winter vegetable. Selected Musselburgh still holds first place in Northern gardens for quality and hardness.

Fruit Under Glass.

Vines.—Muscats in flower should receive careful attention at this time, allowing a night temperature of from 65° to 70°, with a corresponding rise of 10° to 15° on sunny days. Allow the bunches as much light as possible. Muscats do not as a rule set well under dense foliage. Fertilise with a rabbit's tail or very fine-haired brush. Keep the atmosphere dry and buoyant until the bunches are well set.

The Flower Garden.

Half-Hardy Annuals.—The majority of half-hardy annuals, such as Stocks, Asters, Zinnias, *Nemesia* and *Alonsoas*, should be sown now in the genial temperature of a greenhouse. After germination takes place keep the boxes as near to the glass as possible so that sturdy little seedlings may result, which, after due hardening, may be pricked out into cool frames. Guard against too much moisture. Stocks in particular damp off readily in the seedling stage.

Hydrangea arborescens grandiflora.—Plant beds of this delightful American species now. This variety has proved one of the hardiest and most floriferous of the *Hydrangeas*. It is particularly pleasing during the late summer and early autumn, especially when planted in conjunction with *Fuchsia Riccartoni*.

Spring-Flowering Plants.—Beds containing Tulips, Hyacinths, *Myosotis* or other spring-flowering plants should have the surface stirred with a small hand cultivator. Permanent beds of May-flowering or Darwin Tulips should also have the surface cleaned and fresh soil added.

Border Chrysanthemums.—Where these were rooted in boxes some time ago they should now be ready for transplanting into frames. Plant in a rich compost of old potting soil with a quantity of manure from a spent Mushroom-bed added. This assists in forming strong plants, which will be in fine condition for planting out early in May.

POTATO IRISH KING

A NEW EARLY MAINCROP POTATO.
VERY HEAVY CROPPER. FINE COOKING QUALITIES.

A first-class *White Kidney*, of UP-TO-DATE type, coming in as an early maincrop, and producing a heavy crop of handsome medium-sized tubers of splendid table qualities, flesh white, dry and floury, *strongly recommended*. We were given an AWARD OF MERIT by the R.H.S. for this variety, 1921. Among the several trials made in private gardens, in one instance 2 lb. produced 1 cwt. of potatoes.

Specially selected tubers, hand-picked for seed, Class 1., Irish grown, per 14 lbs., 5/6; per 56 lbs., 20/-.

For other fine Maincrop and Second Early Potatoes, see Barr's Seed Guide, free on application.

BARR & SONS, 11, 12 & 13, KING STREET,
COVENT GARDEN, LONDON, W.O.1.

WITH the decline in costs of production, cheaper coal particularly, and ANTICIPATING A REDUCTION IN POSTAL RATES, at the time of despatch, we are reducing the prices of our

Early Flowering Chrysanthemums.

At planting time (about May 1st) we will send one dozen Early Flowering Chrysanthemums for the garden for 5/-, 24 in 12 varieties for 9/-, 50 in 25 varieties for 16/-, 100 in 50 varieties for 30/-, or 100 in 25 varieties for 25/-.

THE BEST PLANTS. THE BEST VARIETIES.

SITUATION VACANT.

CAN ANY LADY RECOMMEND a first-rate single-handed GARDENER, where help is given?—Reply, by letter only, to THE DUCHESS OF WELLINGTON, Ap-ley House Piccadilly, London.

REFERENCE was made on the "Notes of the Week" page a fortnight ago to the exploded May-planting fetish for Hollies, Yews and evergreens generally, which are much more easily removed and established in early autumn. It must, however, be admitted that there are plants which remove most satisfactorily in spring, when growth has started. Two of the most notable examples are the garden Pyrethrums—varieties of *Pyrethrum roseum*, or *Chrysanthemum coccineum*, as it is now known—and the several genera of giant grasses which gardeners group together as Bamboos.

The Pyrethrums.—The time has come to order Pyrethrums, while it is still early for the Bamboos, so that it is the Pyrethrum that merits this week our attention. This is not a deep-rooting plant and is, for that reason, readily injured by drought on badly cultivated soils. Thorough and deep cultivation should, therefore, be the rule, and a good dressing of farmyard dung or of Wakeley's Hop manure should be incorporated. The Pyrethrum resembles the herbaceous Phloxes in this—that it does not succeed if replanted as large clumps. Many gardeners like plants from pots, but there is really no objection to sound first year plants if they are so packed and cared for as to prevent their roots becoming dry in transit. The Pyrethrum, though it abhors drought, dislikes a waterlogged soil, but if the drainage be adequate and the soil well cultivated, it will flourish in almost any type of loam, although it undoubtedly prefers one somewhat light in texture. The great value of the Pyrethrum consists in its flowering season, which is just between spring and summer, when few flowers are to be seen in the borders.

A Fine Cut Flower.—It is additionally welcome because it is really excellent for cut flower. A generation ago the energies of the florists who specialised in this flower were directed solely to the production of double varieties, but nowadays the beautiful single forms are most in favour. The double sorts have, however, the merit of lasting longer, either on the

plant or when cut. Some of the best varieties are, dealing first with the double sorts: Carl Vogt and Aphrodite, both pure white; Lady Kildare, Pericles and Wega, buff shades; Alfred Kelway and Captain Naros, crimson; and Ne Plus Ultra, bluish pink. Among the singles Snow White and Queen of Whites are excellent and pure in colour; the best pink is probably Rev. W. Cuff, but it seems now difficult to procure, so one must be content with the very dissimilar Hamlet to represent this colour. Deeper in colouring, we have Enchantress and Apollyon, and deeper still—a shade of carmine—Mrs. Bateman Brown (largely grown for market) and Bruce. Of crimsons the brightest is still James Kelway, but King of Spain is a larger flower. Propagation is easy, consisting merely in dividing up into single crowns, preferably under a light, immediately second growth commences after flowering.

A Useful Vegetable.—It is strange that the recently evolved intermediate type of Beet has not achieved wider popularity. Even on deep soils, where it really succeeds, the long type is a troublesome vegetable to lift, bearing in mind that a very small scratch will render useless the best of roots. The new type—"oval," it is sometimes not inaptly called—grows largely above ground, like its cousin, the Mangold, which makes harvesting a pleasure instead of a labour. It is

a mistake, especially on light soils, to delay the sowing of long or intermediate Beet too long. Neither is really prone to "bolt," and, all things considered, the first half of April is the most satisfactory time to sow. The Beet is a gross feeder and appreciates rich soil, nor will fresh manure be detrimental to the newer type, so that it be buried a good spit deep. The quality of the "oval" type leaves nothing to be desired, and this strain should follow the stump-rooted Carrot into ever-increasing popularity.

Asparagus Planting.—The season has returned when new Asparagus beds may be planted and old ones—providing the blanks have been marked—may be repaired. On heavy soils, slow to drain, the extensively drained, raised bed so universally met with is imperative; but there are many gardens, where the natural drainage is sharp, where much better results would be obtained by well trenching and enriching the ground and planting on the flat. This method has the great advantage of allowing more space to be allotted to the crowns. Eighteen inches between these and 4ft. between the rows is a suitable distance, and for the first season or two the space between the lines may be profitably utilised for catch-crops of various sorts or for pricking out Brussels Sprouts, Cauliflowers or such like, or the various hardy biennial flowering plants when ready.

A Beautiful Rockfoil.—

Of all tufted (*Kabschia*) *Saxifraga* *S. apiculata*, which forms the subject of the illustration on this page, is probably the most useful. Very early to flower—one of the earliest of all—and extremely free flowering, its sulphur-coloured blossoms seem, somehow, more cheering and spring-like than the cold white-platters—beautiful though they are—of *S. Burseriana*. *S. apiculata* is, moreover, a far more rapid grower and a much more accommodating plant than the *Bursar Saxifrage*. It will thrive in any well drained soil and is, indeed, almost as easy as an *Aubrietia*. There is a pure white variety, which perhaps differs slightly in habit of growth, but is equally floriferous. It lacks, however, the substance and satiny texture of all the several forms of *S. Burseriana*.

THE EASY, GRACEFUL AND BEAUTIFUL SAXIFRAGA APICULATA.

DAHLIAS TO DECORATE THE GARDEN

A well known amateur grower describes what he has found to be some of the best sorts for the purpose.

THE present period may be regarded as most opportune for considering the value of the Decorative Dahlias, as the time will soon arrive when it will be necessary to order young plants from the trade specialists. All too frequently Dahlias are acquired much too late in the spring, and, in consequence, results are less satisfactory in the flowering period than they might be were the plants obtained earlier.

In dealing with the Decorative Dahlias, I propose to regard the term "decorative" in its broadest and most comprehensive sense. There are many types of the Dahlia, and each type has its characteristics defined by the National Dahlia Society, and more recently by the Royal Horticultural Society, at a conference of growers, held at the Wisley Gardens of the latter Society last autumn.

For the purpose of these notes I propose to include within the category of "decorative," Dahlias of different types, each of which has a value in the garden. My object is to give prominence to plants that are especially valuable for garden embellishment, irrespective of how they may be regarded by those who grow this plant solely for exhibition.

Decorative Dahlias for the garden in my opinion should include most of the Pæony-flowered varieties, as well as those of the so-called "Decorative" type. I purpose including in the same category some of the more interesting varieties of the Pompons, Singles, Collarette and the refined and beautiful Star Dahlias, a large number of which may be regarded as ideal for display in beds and borders outdoors and for cut flowers. A somewhat limited number of the Cactus Dahlias may with advantage be regarded as decorative, although the majority of the highly attractive flowers of this type set up at the leading exhibitions in triangular form on wires are almost worthless in the garden. The rule adopted two years ago, and since continued by the joint Floral Committee of the Royal Horticultural Society and the National Dahlia Society, to the effect that "all Dahlias submitted to the Floral Committee for certificate shall be exhibited without artificial support," is indeed a wise enactment. Since this rule has been enforced weak-stemmed flowers have failed to gain the coveted award of merit, this honour being conferred only on flowers with stiff, erect flower stems, which carry their flowers well above the foliage of the plants and which render them highly decorative as a consequence. It is a matter for much regret that raisers of the Cactus Dahlias have for so long worked on wrong lines, utilising plants for breeding purposes having stems incapable of maintaining their flowers in erect position, with the result of bringing into being a progeny perpetuating the same undesirable characteristics. Raisers must mend their ways by working on other lines, so that flowers having weak stems may be eliminated.

For bold, imposing displays in the garden the Pæony-flowered and Decorative Dahlias are to be preferred to other types of the flower; and of these two types I have a distinct preference for the former. This partiality for the Pæony-flowered kinds is probably due to their less formal flowers; as a matter of fact, they are mostly very large, semi-double, with broad florets of good substance and are represented in a wonderful

array of glorious colours. As plants for the garden, individually or grouped in the border, or in beds by themselves, these Pæony-flowered kinds are magnificent for several months, beginning at the end of July and continuing until severe frosts cut them down. Last year the plants continued to flower well into November. Their height varies between 3½ft. and about 5ft. A few of the better Pæony-flowered Dahlias are Albina, pure white, 3½ft.; Luva, bright yellow, 4½ft.; Martial, brilliant scarlet, 4ft.; Hon. Mrs. Phillips Roberts, rich bronze, suffused rose, 3½ft.; Mrs. Nockolds, rich coppery bronze, 3½ft.; Oriana, pure rose, 4ft.; Liberty, scarlet crimson, 4ft.; Apollo, rosy crimson, 5ft.; and Libra, bright rosy red, 4ft. The miniature Pæony-flowered type is exquisite. Generally, this comparatively new section is much admired. The plants are not so large and vigorous in growth as are those of the big flowers, and they yield an abundant display of most dainty blossoms, invaluable as cut flower and beautiful in the garden. There are not many varieties in general cultivation, and the most noteworthy are the following: Norah Bell, scarlet flame, yellow base, 3ft.; Our Annie, shrimp pink, tinted yellow, very pretty, 2½ft.; Chrissie soft rosy pink, 3½ft.; Oriole, brilliant orange scarlet (this variety is sometimes described as a "Star" Dahlia), 3ft.; Edith Jones, salmon pink, shaded gold, 4ft.; and Olivia, deep rose pink, 2½ft.

Decorative Dahlias (so classified) are now becoming quite numerous, and it is not easy to restrict the selection to, say, nine sorts. These have double flowers, of good form, and not seldom they are exceptionally large. The plants make a very striking display, either individually or when grouped in masses. The following sorts are worthy of notice: Mrs. A. Cobb, soft flesh pink, on wiry stems, 4ft.; Delice, rose pink, 3½ft.; Queenie,

golden amber, tipped salmon red, 4ft.; President Wilson, brilliant scarlet, very large, 3½ft.; Sulphurea, sulphur yellow, 4ft.; Warneford, pure white, should be partially disbudded, 5ft.; Portbos, violet mauve, very distinct and free, 4ft.; Mrs. W. J. Unwin, delicate pink, tinted white, very free, 4ft.; and Papa Charmet, deep crimson, huge flowers, 3½ft.

No collection of Decorative Dahlias could be considered complete without the inclusion of a few of the refined Star type. They are flowers of comparatively recent introduction, and Messrs. J. Cheal and Sons have been singularly successful in raising and introducing many of the better sorts. The flowers are borne in profusion on wiry stems, and the plants in most instances possess a beautiful bushy habit of growth, when grown in proper fashion. I have a distinct preference for the following varieties: White Star, semi-double flowers of the purest white, with orange yellow centre—like a Water Lily—4ft.; Yellow Star, yellow, of beautiful form, 4ft. Surrey Star, described as tangerine, suffused with copper and rose, 4ft.; Western Star, rich salmon pink, 4ft.; Southern Star, a combination of crimson, apricot and purple tints, 3½ft.; and Crawley Star, the original of the type, a beautiful clear rose pink, 4ft.

A few Collarette varieties should be in all collections where space can be found to accommodate them. This type of the Dahlia produces its blossoms quite freely, and the plant is most effective in the border. Last season I noted the following varieties for their effective display: Bonfire, orange scarlet, yellow collar; Ustane, salmon scarlet, yellow collar; Diadem, rosy pink, white collar; Eden, pure white self; Admiral, blackish maroon, pure white collar; and Colleen, white, suffused rose, pure white collar. These Collarette Dahlias vary from 3½ft. to 4ft. in height.

THE DECORATIVE GARDEN DAHLIA IS AN INVALUABLE STOP-GAP IN THE BORDER.

Although the little Pompon Dahlia is a distinctly formal flower, I have a great liking for it, as the blossoms stand wet weather very satisfactorily and they are borne quite freely on erect stems. They are good garden plants and generally possess a splendid habit of growth. For garden purposes the following six sorts are useful: Bacchus, scarlet, 2½ft.; Nerissa, soft rose, 3ft.; Ruby, ruby crimson, 3½ft.; Tommy Keith, red, tipped white, 3½ft.; Electra, deep orange, 3½ft.; and Ideal, pale yellow, 3ft.

No type of the Dahlia is more profuse in its blossoming than the Single-flowered, and of these there are many superb sorts. I grow, among others, the following kinds: Lady Bountiful, deep rosy pink, 3½ft.; Owen Thomas, crimson scarlet, tipped yellow, 4ft.; Norma, rich crimson scarlet, 4ft.; Lilian, rosy

lilac; Althea, buff, 3½ft.; and Cardinal, cardinal red, 3½ft.

Small Decorative Dahlias are represented by a restricted list, and the following are especially good: Crimson Flag, dazzling fiery crimson, 3ft.; Reginald Cory, crimson and white, very striking; and The Maid, pure white, 4ft.

The flowering quarters should be deeply dug in good time, so that planting may be done during the first week in June, after first carefully hardening off the plants. A space from 3ft. to 4ft.—preferably the latter—should be allowed between the Peony-flowered and Decorative kinds, and 3ft. or rather less for the other types mentioned in these notes. Procure the plants in good time, pot them up into 4½in. pots, and stand them in cold frames until thoroughly hardened off. D. B. CRANE.

SOME UNUSUAL BUT BEAUTIFUL ANNUALS

AN unusual annual, something out of the common, something fresh, whether hardy or half-hardy, has a special appeal to all flower lovers.

Not only does it feel good, when visited by friends, to be asked, "That is pretty; what is it?" but it adds to one's own pleasure in the garden year to watch the growth and development of something that is unknown and new—at least to us. By directing one's search for this among the annuals there is but a brief period of waiting before seeing the result, either to appreciate a novel treasure or to cast it aside as not of sufficient interest to be repeated. This, however, is unlikely to happen to many of the varieties noted here. Some years ago, I vigorously took up the study of annual flowers, and I think it is safe to say that there are but very few that I have not sown, grown and flowered. Catalogues and lists were exhaustively searched, and, among the results, I discovered a large number of choice and charming things which, somehow or other, are passed by in ordinary selection, simply because they are unknown. A name conveys very little after all, and few lists are disposed to be effusive except in the case of "popular" flowers. If a striking edging plant is wanted *Venidium calenduleum* should be tried. This is one of the grandest brilliant orange flowers that one can possibly find, yet I have only met it twice outside my own garden. The little plants are very dwarf, though

spreading widely, and, in a sunny warm place, cover themselves for months with daisy-like vivid flowers that are remarkably showy. *Flora's*

ONE OF THE HARDIEST OF HARDY ANNUALS—SILENE ARMERIA.

Paint Brush (otherwise *Cacalia coccinea*) is very aptly named, for that is exactly what it is like—a small paint brush dipped in vermilion. The plants are half a foot high, quite hardy and not very vigorous, so that the seedlings should not be too rigorously thinned. A packet of *Dimorphotheca*

pluvialis may be sown in the cool greenhouse now, for planting out later. It grows about 1ft. high and bears a succession of single white marguerite-like flowers with golden centres. The reverse side of the petals is a brilliant maroon.

In a damp, shaded place, scatter a few seeds of the Violet Cress, *Ionopodium acule*. It is a charming little thing that thrives where few other annuals would grow, spreading into dense tufts of foliage, smothered with tiny pale lilac flowers. It is very useful among rough steps in the hardy fern garden and, once sown, usually repeats itself freely year by year. The demand for showier flowers has almost ousted the old-fashioned Night-scented Stock nowadays, inasmuch that it is entitled to take its place among an anthology of unusual annuals. Yet what a treasure it is as evening draws on and it commences its work of attracting the needful night-flying moths and insects. Quite a small clump leaves you in no doubt as to its whereabouts, even at a distance of many yards. No one could accuse the ever-useful *Nasturtium* of being unusual, its bright flowers and free seeding see to that, yet the varieties with variegated leaves (the variegation is distinctly an added charm) are scarcely ever seen. A packet of rosy scarlet, sown during April on the hardest, poorest, hottest, driest soil one can find, will produce a wonder bed from June to October of close, compact, dwarf little plants, perfect balls of variegated leafage that do not break out into straggling trails, with an amazing wealth of gorgeous scarlet blooms that never seem to cease. Another night-scented plant is *Schizopetalum Walkeri*, which might be called the Lace Flower, for it is lace which the remarkable little flowers resemble—wee squares of white lace fantastically cut into exquisite tracery and scenting the whole air in its neighbourhood with a powerful fragrance of almonds. It is half-hardy, but must be sown where it is to bloom, as it is literally impossible to transplant the seedlings, so that sowing should be deferred until mid-May for the open ground, or pots must be employed. Fortunately, late sowing does not matter, as the plants grow and mature very quickly. An annual Stonecrop which is sure of a welcome in the rock garden is *Sedum caeruleum*, a cloud-like little plant with reddish stems, smothered with masses of lilac blue flowers. The best way to ensure success with this is by sowing sparingly in shallow seed-pans, and transferring the resultant plants bodily to the open in late May. *Nicandra physaloides*, a Peruvian annual that is safest when treated as half-hardy, is but seldom seen in gardens. It is a tall and vigorous grower, reaching 5ft., with purplish black stems and soft azure blue flowers that are followed by bladder-like calyces, enclosing large green berries.

I renewed acquaintance last year with *Amarantus tricolor splendens*, one of the most vivid of all annual foliage plants for the greenhouse, that puts many of the *Colcus* into the shade for sheer colour intensity. The leaves are long and narrow, produced alternately round a central stem, and show all colours from green through yellow to vivid blood crimson: a plant to mark when well grown. Blue Beard, one of the Sage family (*Salvia Horminum*), makes a notable addition to the hardy border, for each plant, with its rough sage-like leaves, branches freely, and behind each flower is a sheath-like leaf boldly tipped with royal purple, giving the plant a unique appearance, solely due to this peculiar leaf pigmentation.

Let us turn again to the rock garden for a moment and see where we can scatter a small packet of *Eschscholtzia caespitosa*. I first saw this at Kew, and the following season tried it in my own garden. It is quite unlike any other variety of these gorgeous Californian annuals.

Barely 6 ins. high, with narrow glaucous grass-like foliage, it covers itself with the smallest buttercup-yellow *Eschscholtzias* which it is possible to imagine. It is a gay little flower and worthy of the choicest places. Few who knew the name of a wee plant that resembled the tiniest mossy Saxifrage of which they could think would be slow to sow it, especially if they happened upon it when at the zenith of its beauty absolutely smothered with equally wee orange flowers. Its name is *Leptosiphon aureus*. If a wider range of colours is desired, these can be had in various shades of pink, yellow and white. In the summer alpine garden it is one of the most exquisite little annuals I know, lifting myriads of its dainty little blooms to be kissed by the sun.

On first seeing Lobel's Catchfly (*Silene Armeria*) one is immediately aware of an unusually vivid rose pink flower, but closer examination is necessary to appreciate the unusual character of the plant.

It has glaucous green foliage and is absolutely hardy. It may be sown in the open ground at any time during spring. The stems below each joint are viscid. From these sticky bands the plant gets its name of Catchfly. Upon flowering specimens one can usually find quite a large number of small flies, captured and held in exactly the same way as the fly-paper catches them in a house.

I do not pretend to have been exhaustive; there are numbers of really charming and unusual annuals that well reward the seeker, but the article may serve perhaps to introduce to you something that you had not hitherto seen, and, better still, may start you experimenting on your own account. If this is so let me assure you, that you will not have sought in vain. There is plenty of loveliness and beauty disguised behind a Latin name within the pages of a good seed list
H. W. CANNING-WRIGHT.

varieties are The Geisha, orange-crimson and golden-yellow; Queen of the Buffs; Ruby King, which is dwarfer than the majority of varieties; Rosy Queen; The Rajah, purplish carmine; The Mikado, orange-crimson; Carmine King; Mandarin, orange-crimson and deep orange; Vesuvius, deep crimson; Frilled Pink and Rose Cardinal, creamy Rose. Mixed seed may also be obtained. Apart from the varieties named above, some of the species are exceedingly attractive. Among these are californica, pale yellow; crocea, orange; and its many varieties
H. G.

A HEAT-LOVING ANNUAL

ALTHOUGH strictly perennial, that Californian Poppy, the *Eschscholtzia*, is generally grown as a hardy annual, a mode of cultivation which gives very gratifying results.

For bedding purposes the genus *Eschscholtzia* affords some striking varieties which are conspicuous from afar. During the past few years many beautiful varieties have been introduced and these, or some of them, should find a place in every garden, large or small.

The illustration depicts a border of mixed *Eschscholtzias* growing on a dry bank, fully exposed to the sun. The photograph was taken last summer when the drought was at its worst. In this particular instance the plants were growing in poor sandy soil. It will be seen then that this brilliant Poppy is not fastidious as regards soil and position and above all it is a drought-loving plant. By sowing seed within the next week or so where the plants are to flower a bright display of blossom will be forthcoming during the summer months. When the seedlings appear they should be well thinned out. Apart from their value as bedding plants and for banks they are equally useful as border plants. They should, on account of their habit, be planted at the front of the border.

Eschscholtzias provide excellent cut flowers for house decoration, but this, unfortunately, is not so generally known as it should be. It is best to cut

the blossoms early in the morning before the buds expand. They will then last for several days in water. The varieties differ little in height, which averages about a foot. Some of the best

A SUCCESSFUL BORDER OF THE DROUGHT-RESISTING
ESCHSCHOLTZIAS.

THE PERPETUAL CARNATION

Hints on propagation; its value outdoors and in.

IN these days when economy has to be practised in every possible way, and the high price of fuel has resulted in many old favourite plants requiring a considerable heat being dispensed with, the question arises as to what is the best and most economical plant to grow in order to provide flowers all through winter.

For this purpose nothing can surpass the Perpetual-flowering Carnation, which will produce choice flowers in a temperature that can easily be maintained by anyone having the smallest amount of heat in the greenhouse. The plants themselves are perfectly hardy, but to get the best returns a minimum temperature of 45° should be maintained while admitting a little air through top ventilators on every possible occasion. A temperature of 47° is ample at any time as a night temperature with a rise of a few degrees in the daytime.

If no old plants are available from which to obtain cuttings, now is the best time to order young plants from a reliable firm of Carnation growers. Trouble taken to procure the best is amply repaid later on. Cuttings are best rooted in January, but quite good plants can be obtained from cuttings rooted now.

The quickest and easiest way to root them is to insert them in pans of sand and place them in a frame where slight bottom-heat can be obtained. Keep the top temperature several degrees lower to prevent cuttings becoming drawn and weakened while rooting. Most varieties will be rooted in about three weeks. The pans should then be lifted out of the frame and allowed to harden in more airy surroundings for a week before potting. On no account let cuttings become dry in the sand or failure to root will result.

The cuttings should be potted into 2in. pots in a compost of loam, leaf-soil and sand. When roots are nicely through to the sides, repot them into 4in. pots, adding a little lime rubble and wood-ashes and reducing the quantity of sand. Keep the plants sturdy and short-jointed by admitting as much light and air as possible.

When the plants are established in this sized pot most of them will be ready for stopping, which should be done when they have made about ten pairs of leaves. Stop back to six joints, when a good break from every joint should result.

When the shoots have made six pairs of leaves they should be stopped again, but not after the middle of June for slow-growing varieties and July for quick-growing sorts. It is wise to stop only one shoot on a plant at one time, as the "spread-over" prevents plants receiving a check and also provides a succession of blooms later on.

The final potting should be into 6in. or 7in. according to size of plants, using a mixture of

good loam, a little well rotted manure, lime rubble, wood-ashes and a sprinkling of sand.

The plants may be stood outside during the summer, but protection from heavy rains should if possible be afforded. Do not leave outside after the second week in August. Varieties that

are subject to rust are best grown under cover all the year.

When the plants are housed give them a top-dressing with some special Carnation manure and an occasional sprinkling at intervals, taking care not to overfeed them through the dull days of winter.

In April, if plants are not required to flower in the houses, they may be planted outside, where they will continue to flower all summer. If planted in beds or borders they flower well until late autumn. If an edging is required, the *Allwoodii* are very suitable. S. A. PASCOE

NATURAL GARDENING IN A RESTRICTED SPACE

Some Hints on Planning and Planting.

IT has often been stated in these columns that for the small garden a more or less formal treatment is most satisfactory and effective, but there is no gainsaying the fact that the whole ambition of many small gardeners is concentrated on providing informal effects, largely by the use of small rock gardens. Certainly, if the air be reasonably pure, rock gardening has two great advantages for the small garden. The first is that the excavations and mounds necessary to this form of gardening really enlarge the space at disposal, since plants are set to grow in the vertical cliffs as well as in the more or less horizontal beds and "pockets." Again, some choice alpine plants are exceedingly minute, while the larger rock plants are, compared to many forms of vegetation commonly grown in gardens, quite small. A larger variety with a considerable season of blossom can therefore be provided even in a tiny garden.

It is a fact that the bulk of true alpines flower in spring, but there are many plants suitable for the rockery which flower at other seasons. Among these the Hardy Heaths take high place, but there is no need to describe them in detail here as articles on the family have recently appeared in *THE GARDEN*. Winter-flowering Irises, such as *I. reticulata* and *I. Danfordia*, and, at any rate, in the west, *I. unguicularis* and varieties, will join up with such early-flowering *Kabschia Saxifrages* as *S. apiculata*, *S. Boydii alba* and *S. Burseriana*, and the Glory of the Snow (*Chiono-doxa*) in several species. With our thoughts on bulbous plants it may be well to mention how lovely here are such things as some of the tiny Narcissi. Some of the best are *N. minimus*, *N. Bulbocodium*, with its variety *monophyllus*

THE TINY WILD GARDEN AT THE IDEAL HOME EXHIBITION, CONSTRUCTED BY MESSRS. R. WALLACE AND CO.

and *N. triandrus*. These flower, it is true, when alpines generally are waking from their winter sleep, and the same applies to the lovely *Anemone blanda* and to a greater extent to the even bluer *A. appennina*, to the Snakesheads (*Fritillaria Meleagris*) and to some of its not more lovely but rarer consins, to the Dog's Tooth Violets (*Erythronium*), including the magnificent Pink Beauty and the fragile and chaste White Beauty.

The Alpine Pinks are valuable inasmuch as they extend a little the season of flower, when *Aubrieta*, *Arabis*, *Alyssum*, *Alpine Phlox* and *Gentian* are past their best. The same may be said of the almost ever-flowering *Lithospermum prostratum*.

Later in the season flowers are scarcer, but besides the Hardy Heaths, already referred to, including of course, the Irish Heaths (*Daboecia*) and several other American plants of minor interest, there is the deep rose *Silene Schafta* and, in shady corners, the *Pinguiculas* will add interest. As autumn comes along the hardy *Cyclamens* form an attractive feature, so that, the year round, there need be no want of interest.

On the arrangement of the stones largely depends the sum total of effect, and here attention has to be focussed simultaneously on two objects. These are the welfare of the plants and the pleasing and probable disposition of the stone masses.

The very pretty, if very tiny, rock garden, illustrated herewith, was built by Messrs. R. Wallace and Co. at the Ideal Home Exhibition at Olympia. Every gardener could find room for such a rock garden and yet it must be admitted that it is quite effective without being tussy.

Back to back with this little rock garden the same firm had on view a miniature wild garden which is one would think, the "smallest ever" yet so beautiful is the contouring and so well balanced the planting that it forms a perfect little picture. Such a feature, preferably on a rather larger scale, might well be associated with a rock garden similar to the one shown, but care must be taken not to overplant this type of garden. Plant such a garden solid whether with *Muustead Polyanthuses*, with *Daffodils*, *Fritillarias*, or plants of larger growth, and the picture is completely destroyed.

THE LITTLE ROCK GARDEN AT OLYMPIA, ALSO CONSTRUCTED BY MESSRS. WALLACE.

THE MODERN GLADIOLUS

The queen of summer-flowering bulbs can be planted from now till the end of April or, for late bloom, up till the third week in May.

SOMETIMES devolving through devious ways, anon travelling the blissful avenues towards the delectable mountains, I have at length journeyed my Hadj and am arrived at the Mecca of my desires; which, being interpreted, means that through years of seeking and collecting, and the gaining of knowledge (often by faults and use-less expenditure), I have at length gathered around me a veritable museum of the world's best Gladioli—a museum now indeed, for the dormant corms are hardly, to casual glance, more alive than the treasures of the numismatist or the philatelist. But planting-time is at hand, and these dried lumps of root-stock will in due season break their chrysalides and emerge as a fairyland of butterfly beauty.

Always a lover of Gladioli from the time when, as a small boy—though, I will warrant, keener on hunting Indians among the wonderful sand dunes of Prestwick on the Ayrshire coast—I looked forward to frequent visits with my father to the nurseries of Messrs. Mair and Sous, some half a mile or so from our house. In those days Mair's Gladioli were, as they are to-day, a very celebrated lot, but memory has left no record of what the flowers were actually like beyond a Turneresque vagueness of colour, such as one

gets in thinking of those masterpieces "Ulysses deriding Polyphemus" or "Rain, Steam and Speed." Doubtless *gandavensis*, *Nanceianus* and *Lemoinei* were all represented, and even in this year of grace these names are all that many people think of when ordering Gladioli, though Kelway's and Groff's hybrids are now well known to interested growers, and they have certainly greatly improved the standard of the large-flowered types in recent years.

We can now, however, abolish all these derivative proper names, and, for the sake of simplicity, classify the summer-flowering Gladioli under two headings only—large-flowered and *primulinus* hybrids. The latter have become a powerful factor and may be said to be responsible for the reawakening of a wide interest in this queen of summer-flowering bulbs. The story of *G. primulinus* and its subsequent history of hybridisation is too well known now to be repeated here, but no one desiring the best effects from planting these bulbs can afford to ignore this graceful and lovely race. Messrs. Kelway of Langport list some choice varieties of their own raising under the name "Langprims," some of the most beautiful being *Ella Kelway*, palest yellow with rose shading; *Ghost*, canary yellow self; *Golden Girl*, a fine pure yellow; *Lieutenant Kelway*, a

highly coloured flower of nice shape, reddish salmon, shaded crimson; and *Phyllis Kelway*, another pure yellow. The best *primulinus* hybrid yet raised in this country, however, is *Major Churcher's Woodcote*, one of the grandest of the whole race. The colour is a soft pastel tone of coral scarlet with cream blotch on lower segments, while the shape of the blooms and disposition on the graceful spike are very near perfection.

Many of the Dutch originations are excellent; *Orange Brilliant*, *Sunrise* and *Maiden's Blush*, while low in price, are extremely lovely, other outstanding sorts being *Insurpassable*, *Kitty Grulllemans*, *Scarletta* and *Niobe*. America undoubtedly claims pride of place with regard to the production of new Gladioli generally, and they are certainly not behind with *primulinus* hybrids. To mention only a few we might quote *Alice Tiplady*, orange saffron; *Altair*, salmon saffron; *Avatrix*, a glorious combination of amber and delicate rose; *Canopus*, a fine yellow self; *Enon*, orange and yellow beautifully blended; *Fulton*, an exquisite thing with ruffled petals, the upper ones salmon rose and the lower deep gold veined with rose; *Nydia*, the perkier, daintier little flower imaginable, decked up in primiest apple blossom pink and rose; *Otranto* the most lovely yellow I have yet seen,

the bright red throat markings enhancing the aspect of the whole flower; *Salmon Beauty*, most truly named; *Sweetheart*, deliciously blended cream and gold; and *Topaz*, a graceful and elegant aristocrat in buff and salmon.

Among the large-flowered type there is such an array of talent that it would take a whole page to do justice to even a limited selection.

A CHARACTERISTIC SPIKE OF THE NEW LARGE-FLOWERED RUFFLED SECTION.

A TYPICAL GLADIOLUS PRIMULINUS HYBRID.

Three Kelway sorts come to mind at once—*Field Mouse*, Kelway's *Painted Lady* and *John Churchill Craigie*. *Field Mouse* is quite fascinating in colour, a sort of smoky old rose overlying red, with a crimson-scarlet blotch; the *Painted Lady* is pure white with very prominent crimson blotch, and the last is a lovely soft salmon with a large yellow blotch. Mair's *King George* is a good handsome flower of great substance and a large spike, deep crimson with a snow-white blotch.

Of the American varieties I shall be better able to speak in the autumn, as we are planting up a very fine selection of them presently. I cannot help, however, mentioning again Kunderd's *Byron L. Smith*, in some ways the loveliest flower I have ever set eyes on. Mr. Kunderd, by the way, tells me he has a *primulinus* hybrid of similar shade coming out in a year or two. The day when I can receive that I await with impatience and excitement "beautifully blended." *Byron Smith* is lavender pink—so is America. I never could stand, much less enthuse over, the latter—such is the poverty of our colour descriptions! One is an ethereal goddess and the other a very common flower, both described by the same words—well, well! Mr. Kunderd has many stars in his cast which I hope to gossip on more at length after the flowering season is over. By a charming act of friendship on the part of Mrs. Francis King, the American authoress, I am planting up some new introductions of Mr. J. A. Kemp, a New Jersey grower of some repute. His *Pink Wonder*, *White Wonder*, *Albania* and

Early Snowflake have proved widely popular already at the various American shows, and I hope to have the opportunity of exhibiting these and many others at Vincent Square this year.

The culture of Gladioli is extremely simple. With good corms and a modicum of common sense, success is practically a foregone conclusion. Any well worked, deeply dug and fairly rich soil will grow them well, whether the medium be light or heavy. It is well worth while taking the little extra trouble, when placing the corms in the ground, to surround each one with an envelope of silver sand and crushed charcoal; if the latter is not handy, then with coarse sand alone. In heavy land the tops of the corms should be 3 ins. to 4 ins. below the surface, in light soils about an inch deeper. On no account should fresh manure be dug in just before planting, but a mulch of stable or farmyard litter in early June will conserve moisture, help to build up a good flower spike and assist the formation of the new corms which, during the growing season, supplant the old ones.

and climate enter so largely into the question but it will be some sort of a guide to mention that the majority of varieties bloom from seventy-five to ninety days after planting; a few early sorts, like Prince of Wales and Halley, will reach maturity in seventy days in a warm season, while Princeps, Panama, America and some others oftentimes require over a hundred days.

Considerable interest is being shown in our new

method of flowering Gladioli from seed in six months, and there is undoubtedly an immense amount of pleasure derived from growing one's own hybrids. Cross fertilisation is quite a simple matter, and if a few really good varieties are purchased so that a crop of reliable seed can be saved there is no need whatever to wait four or five years for results, as one has always been taught to believe.

J. L. GIBSON.

THE SPRING CARNATION SHOW

THE BRITISH CARNATION SOCIETY held their twenty-seventh Show of British grown and mostly British raised Carnations on March 21st. That the hall was almost filled with Carnations, all of considerable merit, speaks volumes for the perfection of cultural methods and the value of the flower. From the spectacular point of view,

always is a *but*, and in this case it is a terrible *but*, the atrocious chorus girl's hat made up of countless numbers of pink and cerise Carnation petals, the Carnation ship and such were perfectly appalling and certainly detracted from the artistry of the trophies that Mr. Felton arranges so splendidly. To mention only one, the small basket of the golden and green foliaged *Croton turnfordensis* and the

RICH IN TONE AND SHAPELY—THE NEW PERPETUAL CARNATION NIGGER.

PROBABLY THE PUREST WHITE CARNATION IN EXISTENCE—WIVELSFIELD WHITE.

Each plant should be staked to prevent damage by rough winds, and the surface soil must be kept open by frequent stirring if no mulch has been applied.

Weak liquid manure may be given frequently for a month or so before the first flower begins to colour, and as an alternative weak soot water or nitrate of soda (two teaspoonfuls to a gallon of water). The last named is useful for heightening the colour of the rich reds and scarlets.

We are sometimes asked when to plant corms so that they will bloom in time for a certain date. This is not easy to answer because environment

it was the new Florists' Class competition that was the great feature of the show. The prizes were on a generous scale. A handsome "Covent Garden Challenge Trophy" and £30 for the first, £30 for second and £20 for third. These were, of course, well worth winning, so that the five exhibits were a goodly array. Except that funeral designs and mirrors were debarred, the exhibitors had perfect freedom of action on their allotted spaces. Messrs. R. F. Felton and Sons, the Hanover Square florists, were the most successful. The arrangement of the various baskets, vases and such was perfectly charming and left nothing to be desired but, there

deep yellow Saffron Carnation was most delightful.

In the second prize arrangement by Mr. N. B. Shearn of Tottenham Court Road, there was a handsome wall bracket of crimson Carnations and a decorative screen of cerise and blush. From a purely decorative point of view, however, the most pleasing of all these various designs was a large basket in the third prize exhibit by Mr. K. Silvester of Sloane Square. This was of mixed Carnations, chiefly of such fancies as Jazz, Sheila Greer and the reddish-brown leaves of *Croton Queen Victoria*, with just the right number of crimson *Thor* rising above them.

The Lady Members' Artistic Classes were disappointing. The first prize table was of Wivelsfield Apricot Carnations, with Croton leaves and sprays of Pittosporum, but the arrangement was very stiff and formal. The few vases and baskets were much of the same character. In the open classes Mrs. Hammond was awarded all five first prizes for very tasteful arrangements.

Sir Charles Hall-Cain, The Node, Welwyn, had three exhibits and won three first prizes. These were all particularly well grown plants in flower and included Lady Alington, Lady Ingestre and Chastity. His group which won the Lord Howard de Walden Challenge Cup was well arranged.

Most of the other first prizes were won by Sir Randolph Baker, whose gardener grows Carnations every bit as well as he does Sweet Peas and is also able to arrange them attractively.

In the open classes it was a case of Mr. C. Engelmann first in almost every case. The principal exception being the class for not fewer than 100 blooms of any one variety which was won by Messrs. A. F. Dutton, Limited, of Ivry, with beautifully coloured blooms of Lady Northcliffe.

The best British novelty distributed since 1919 was the crimson Thor, shown by Mr. Engelmann who, in Topsy, another splendid crimson, had the best American novelty, and this was also very effective in a large vase.

In the colour classes the best varieties were Peerless, rose pink; Aviator, red; Carola, crimson; Laddie, salmon pink (this vase was also adjudged the best in these classes and won a silver-gilt medal for Mr. Engelmann); Saffron, yellow; and Crystal, white.

Several of the principal trade growers arranged magnificent collections around the hall. Mr. C. Engelmann and Messrs. Allwood Brothers both won large gold medals; Messrs. Stuart Low and Co., were awarded a silver-gilt and Messrs. Keith Luxford and Co., a silver medal.

The sundriesmen had quite a field day. Much attention was focussed on the "Willmott" plant stake, which should, we think, be very useful for plants under glass, particularly Carnations, as it combines stake and tie in one and is instantaneously adjusted or removed. Its merit for plants outdoors has to be demonstrated, though Messrs. H. J. G. Wood, who exhibited it, described it as a great success in the flower border. Mr. John Pinches of Aeme label fame had, in addition to the east labels in which he specialises, his new clips for fastening exhibition tubes just where required on the special steel uprights.

NEW CARNATIONS.

ATLANTIC.—This is a Perpetual Malmaison variety, raised in America and "disseminated" in this country by Messrs. Allwood Brothers. It possesses in a marked degree that precious gift of fragrance which one instinctively associates with the Malmaison Carnation and the white petals have just the faintest suggestion of the old Malmaison tint, though they are nearly white. A few blooms showed a hard, displeasing eye, but the best of them are gracefully double, much like a small grandiflora Paeony bloom. The plants which accompanied the vase of blooms were sturdy and floriferous. Award of merit to Messrs. Allwood Brothers.

NIGLER.—The name is somewhat misleading, as one would expect to see an exceptionally dark flower, while, as a matter of fact, several varieties—Carola and Topsy, to mention only two—are darker. But it is a splendid flower and a welcome addition to the crimson sorts. The flower stems are unusually long and it seems to be very free blooming. Award of merit to Mr. C. Engelmann.

TORFADOR. As shown, this is a blush pink Lancy Carnation, freely striped with deep scarlet,

though we should expect these colours to become rather darker in the summer. It is a true Perpetual of good form, free flowering and vigorous. Award of merit to Messrs. Allwood Brothers.

WIVELSFIELD WHITE.—This good white Perpetual Carnation had already received the R.H.S. award of merit. It is the whitest of the white Carnations and has all the appearance of a bloom that will continue fresh for a considerable time in a cut state. The raisers claim an "Old Clove fragrance" for it, but we could not detect any, though perhaps the cold weather was responsible. Award of merit to Messrs. Allwood Brothers.

ALLWOOD'S VIVID.—This Perpetual variety was decidedly the brightest Carnation in the Show. The intense glowing colour seemed to vibrate and almost dazzle one. It is chiefly scarlet-cerise with a sheen of rose on some of the incurving petals. We suspect that its form was against it with the judges, for it did not receive any award, but the quaintly crimped appearance of the petals appealed to many visitors who were first attracted by the brilliancy of the colouring. It is a free flowering variety and more than likely to become popular. Shown by Messrs. Allwood Brothers.

SWEET VIOLETS

How to keep the stock strong and healthy.

JUDGING from the great numbers of bunches of splendid flowers seen in the markets and in private gardens this spring the Violet is again becoming very popular. It is truly an amateur's plant. Even in the smallest garden there is room for a few plants both in frame and open border. The season has now come to propagate the plants by means of layers or runners, as they are sometimes called. Early layering of runners must be carried out on old plants growing in frames. These old plants must be kept quite clean—free from faded leaves and from moss on the surface of the soil. It is bad for the plants and the new runners if the cultivator treads much on the border; such treading can be done without and should be avoided.

On some of the plants—the single-flowered more particularly—the runners are very similar in character to those of the Strawberry, and there need be very little difficulty in pegging them down in the soil. Some of the double-flowered varieties form small plantlets or tufts close to the parent plant, so in their case it will be necessary closely to examine them and to surround the small tufts with a suitable compost in much the same way as one does when engaged in layering the old double-flowered Primulas.

Nice fresh compost should be used. The layers would root in the border soil, but this having been in the frame since last September, will probably be getting sour. It is helpful, therefore, to mix some well rotted loam, leaf-soil and sand together in equal quantities and place a good handful round each runner, mixing the compost with the surface soil of the border.

In the accompanying sketch *a* shows the old plant; *b*, the runner of a single-flowered specimen; *c*, the new compost; and *d*, the peg making the runner secure in its position. Without the peg the runner, when, perhaps, it is partly rooted, may get displaced and root-formation be considerably delayed. Maintain the soil in an even state of moisture and in a very short time roots will form as shown at *e*, in the sketch.

The ground must be deeply dug and enriched with rotted manure; then plant as shown in the following sketch, disposing the young plants as shown at *f* and *g* respectively so as to have equal

space between them. From all plants seed-pods, *h*, must be pinched off; they form freely on some old plants and help to exhaust their strength.

If any plants of the double-flowered varieties are wanted next autumn and winter for flowering in pots in the greenhouse or conservatory it is wise to place the young well rooted layers direct into their flowering pots in spring, and to plunge the pots in the border soil instead of planting them out and then lifting and potting them in autumn. I have found the plan answer well. A little more

METHOD OF PROPAGATING THE VARIETIES OF SWEET VIOLETS.

labour is necessary in regard to potting and watering early in the season, but then there is no potting needed in the autumn. The letter *i* shows the thriving plant in the plunged pot, *j*.

The best position is one in the centre of the garden or on a border west, north west or north-east of a wall. Always avoid a border open to cold draughts, as plants exposed to such rarely escape being infested with red spider.

Princess of Wales and La France, single, and Marie Louise and Comte de Brazza, double, are probably the most satisfactory varieties, though there are other excellent sorts. GEORGE GARNER.

BORDER PHLOXES

Some hints on culture and a selection of varieties.

IT is doubtful whether any other hardy perennial for garden decoration excels the Phlox. Coming into flower in July the plant "carries on" well into the autumn, thus proving a decided adjunct to the flower garden when other flowers, especially bright flowers, are beginning to get scarce. That old species, *P. decussata*, has played a prominent part in giving us the beautiful florists' varieties which we prize so much to-day. The herbaceous Phlox has achieved a large measure of popularity during the past few years, but it is still not so widely grown as its merits deserve. This, no doubt, is due to the fact that many people are neither conversant with the better modern varieties nor realise the length of their flowering period. The Phlox is not a fastidious plant, but it is rather a gross feeder and to obtain the best results it should be given a well cultivated position. A good rich loam that has been deeply dug and well manured—old stable manure, thoroughly decomposed is best—will suit the Phlox admirably.

When planting, some sort of colour scheme should be borne in mind and the heights of the different varieties must not be forgotten. There are quite dwarf Phloxes, which must be reserved for the front of the border. On the other hand the planting should not be too formal. Those readers who have visited Kew Gardens during the summer and early autumn will well remember the borders of Phlox, admirably planted in large drifts of one variety, e.g., a large group of Mrs. Jenkins (white) might be followed by a group of W. Watson (pink). A most common mistake is to let the plants grow into very large clumps as from such the flower spikes are never first-rate. Large clumps are best divided up in the autumn, replanting the outer portions and discarding the worn-out central portion. Another error is to loop up too many shoots to one stake, as this gives each group a besom-like appearance. It is better to retain six to eight strong growths—discarding the remainder—and to spread these out and attach to separate stakes.

It is not necessary to have long stakes towering above the plants; all that is required are short stakes which will prevent the shoots from being blown down by wind or rain. Phloxes require copious supplies of water, and a mulch of well decayed stable manure will greatly assist in producing and preserving the pleasantly fragrant blossoms. The value of this mulching was well exemplified during last year's drought, when Mr. Jones repeatedly staged wonderful spikes of blossom at the Royal Horticultural Society's meetings.

Apart from its value for garden decoration, the Phlox is excellent for cut flower, as the fragrant blossoms are generally appreciated in the house, though the tendency of the flowers to shed buns them from the dinner table. The fragrance of the

Phlox is, perhaps, "brought home" to us more when walking in the garden after dusk on a summer's evening.

The best time to plant Phlox is undoubtedly the autumn, but excellent results may be obtained by planting now. The sooner this planting is done, the better will be this year's results.

The following varieties will be found excellent for large and small gardens: Mrs. E. H. Jenkins, Tapis Blanc, Fraülein von Lassberg, all white; Selma, clear pink; Le Mahdi, violet blue; Le Siecle, salmon pink; Eugène Danzanvilliers, soft lilac blue; Etna, a dazzling crimson scarlet; George A. Strohhelm, somewhat similar colouring; Paul Martin, china rose; Dr. Königshofer, brilliant orange scarlet, deeper eye; Baron von Dedem,

THE BEAUTIFUL SALMON-BLUSH PHLOX HANNY PFELEDERER.

scarlet and blood red; Dr. Charcot, blue; Elizabeth Campbell, salmon; Frau A. Buchner, pure white; H. J. Jones, rosy scarlet; William Watson, soft pink, mauve eye; C. Edwards (an improved Aubrey Alder), salmon; Jesse Waters, salmon orange, carmine eye; Hanny Pfeleiderer, salmon-blush; Thor, salmon-red, carmine centre; Rosenberg, fiery carmine-violet with blood-red eye; Imperator, rich crimson; Horrie Freeman, salmon-cerise; W. J. Robinson, deep carmine-red; and Autumn Merce, soft lavender. The above list contains some of the best varieties from the garden decorative standpoint.

When thinning out as already advised, plenty of cuttings will be available. They should be taken in the same way as Chrysanthemum cuttings and inserted in pots, pans or boxes of sandy soil and placed in a cool greenhouse or frame. These cuttings will provide plants for next year. Trade growers of Phlox raise their plants from cuttings, which is the most satisfactory method of propagation. When well established they may either be

planted out where they are to flower or placed in large pots to bloom in the conservatory. Phloxes are ideal for this latter purpose, as they brighten the conservatory at a time when "showy" flowers are scarce. H. Q.

TWO CROCUS SPECIES

Obtain the Award of Garden Merit.

AT their meeting on February 23 the Council of the Royal Horticultural Society gave the award of garden merit to *Crocus Tommasianus* and to *C. speciosus*. Both are good doers and will, with ordinary care, increase rapidly in any well drained British garden. Their only enemies are field-mice and pheasants. Both species produce seed so freely and multiply by the formation of so many small corms that, so long as their foliage is allowed to remain until it becomes brown (about the end of April), permanence and increase are assured. The only attention they require is an occasional replanting when they become too thick. The one brightens the garden in the early spring; the other tones the browns, reds and yellows of the dying year.

Crocus Tommasianus flowers, as a rule, just before most forms of *C. vernus* and about the time of the old Dutch yellow *Crocus*. It has a slender grace that most of the Dutch forms of *C. vernus* lack, and is, when open, of a clear and delicate colour, described by Maw as sapphire-lavender and by Bowles as amethystine-violet. No Dutch *Crocus*, except the one I hold the most beautiful of all, Margot, is so tender and pleasing in shade. When closed the flowers of most forms are of various shades of grey. It is a variable plant, especially, perhaps, in the colour of the buds; but there is a deep purple variety, a pure white, and a particularly pleasing one, called "pictus," with flowers marked at the tips with a darker blotch, below an apical white spot.

Crocus Tommasianus does well in many places at Wisley, in the open and in the light shade of shrubs and trees, but does not prove quite so happy as many in the grass. Its best place is on the higher parts of the rock garden where it may seed down and gladden the early days of dull February with drifts of lavender violet, which will not interfere in the least with the flowers that are to follow after. It should be planted in August or September, and seed should be sown as soon as ripe in the open to germinate with the growth of the corms in the spring.

Crocus speciosus flowers in September and October and is the most reliable and showy of all the autumn-flowering species, unless it be *C. nudiflorus*, great drifts of which form one of the beautiful autumn features of Wisley and which, though so abundant in its easily accessible native home, is scarcely known in the nurserymen's catalogues. *C. speciosus* should be planted in July. It will grow in short grass, where, as at Wisley, it may be left alone for years, and every year will give stretches of blue among the green of the grass and the brown of the falling leaves without any further care. It will grow under light shade and in the open, and is proper for the herbaceous border and the lighter shrubbery, the grassy bank and the rock garden, the edge of the wide woodland walk and the field garden. A strong and vigorous flower, it is calculated to withstand all reasonable buffetings of autumn. In its typical form it is beautifully pencilled with blue on a pale lilac ground, but varies much in colour and size; and a number of names have been given to more or less distinct forms, the most remarkable of which are the var. *Aitchisonii*, the giant of the species and flowering later than

the type, collected by Mr. H. J. Elwes in the East (for while *C. Tommasianus* is more Western in its distribution, *C. speciosus* stretches away into Armenia and perhaps into Persia); Van Tubergen's var. *Artabir*, intermediate in colour and season between var. *Aitchisonii* and the type; var.

globosus, a bluer, later-flowering variety; and some white and grey forms which Mr. Bowles has raised, which are still rare, but beautiful in their blue pencilling on a white ground, and therefore preferable to the better known pure white form, which is rather starchy in shape. F. J. CHITTENDEN.

PLAN THE GARDEN FIRST

The writer urges that architects should take the garden into consideration and design it simultaneously with the house.

WITH the great majority of architects it is the rule to design the house first and the garden afterwards. Almost invariably is this so in the case of suburban property and small villas, while for terrace houses "gardens" are rarely ever thought of. Even where gardens are plotted the architect rarely troubles to plan them, and either leaves the plot bare or allows the builder to do his best (or worst) with the area allotted to the back garden. True, the front garden area is usually dealt with so far as specifying the sort of wall or fence to be erected thereon and the positions of the main and side entrance paths, but rarely is the garden behind planned to its best advantage by the house designer. That this is wrong from every point of view—æsthetic, practical and financial, I propose to prove.

I postulate that a well arranged garden adds appreciably to the value of any dwelling house, therefore it must "pay" the house-owner or landlord to have the most made of any ground attached to a house. Further, I urge that not only does a well planned garden show off the house from the exterior point of view, but it increases the interior values—that is when the garden is planned before the dwelling, and the dwelling sited to command the best view of the garden. I go further and say that the siting of the house should be subordinate to the amenities or possibilities of the garden, and, if necessary, it should be set at an angle, or sideways, or even turned round, with its back to the road! This may not look "pretty" on the "elevation to the road," but if the roadside faces north and there is a prospect of a pretty garden behind, it is the better way. Naturally, the placing of the kitchen and offices on the road side of the house calls for more attention and skill on the part of the architect, but that is what he is paid for. My first proposition, then, is that the house should be sited in relation to the actual or potential garden, and not the garden loosely arranged round the house.

In planning the garden consideration should be given to all its natural features, such as the slope of the ground, if any, as existing trees, or, possibly, a stream; also to any irregularity in its shape. If the house to be erected thereon occupies a corner site, a triangular or an odd-shaped piece of ground, there is both more call and larger opportunity for effective treatment. Needless to say, all trees should be left standing, as far as possible. Where the ground slopes the house should be placed on the highest part, and the dwelling should be so planned that the best view of the garden be obtainable from the best rooms of the house. Where practicable, the kitchen also should command a bit of a view, and the windows not have their outlook on a blank wall; this will be better for the health and spirits of the cook and also for the cooking. In planning the garden it is important that each part of it bear a definite relation to the house and that the lines of these parts be so arranged that the whole is symmetrical and pleasing.

In addition to the æsthetic advantages of a properly arranged garden there are several practical

ones in planning it before building the house. In the first place any excavations such as those for the garden walls, for Lily ponds, for "sunk" gardens or for forming a terrace can be carried out while those for the house foundations are being made, and, further, the soil excavated from them can be carried direct to the parts to be filled in or raised, thus saving the cost of dumping and afterwards carrying the earth for levelling up. Next, if the garden walls are to be of brick, they can be erected at the same time as the house is being built, and by the same bricklayers and labourers—time, cartage and overhead costs all being thereby reduced. Another incidental advantage is that brickbats, broken bricks or pieces of stone could be utilised in the garden construction straightaway, thus saving on the cost of brickwork and the double handling of such waste material from the house in building. Further, if and where concrete is used in the garden construction, for which it has many advantages, the mixing-boards and materials will be handy, and time and money be again saved to the builder or contractor. The use of concrete in forming the garden has the further advantage of utilising odds and ends of brick, stone, slate, tile or other hard substances thrown out by the house-builders and otherwise costing money to remove. Here, again, the necessary cement is probably on the ground, the water-taps in position, and the mixing-boards handy. However, as every contractor knows the saving in costs and charges by doing two jobs at one time, and by the same hands, I need not labour the point.

In planning the garden the careful architect will have taken advantage of any natural features, and particularly the lie or slope of the ground. If he designs a lawn on sloping ground he will probably have more excavated soil than he needs for its levelling; this can be utilised for forming a terrace or a bank at the bottom to divide the flower from the vegetable garden. For it goes without saying that a vegetable plot, however (necessarily) small, should always be included in the garden scheme. Incidentally such division of the garden area does not diminish, but adds, apparently, to its size, while it greatly enhances its amenities. If the site be level it can easily be embellished either by raising a low terrace walk or sinking a shallow Lily pond, or making a miniature "sunk" or Rose garden. This need not be excavated to a greater depth than 18 ins. or even 14 ins. Moreover, it has the further advantage that the excavated earth can be used to form a terrace, thus affording three different levels at one operation; this alone gives distinction to a garden plot even of the tiniest. These differing levels call for steps, another simple, cheap, but effective, feature of garden decoration. Naturally, that economic plastic material, concrete, would be used for forming the sides and bottom of the pool for Lilies or other aquatic plants—nothing adds distinction and beauty to a garden so much as the presence of water.

Another quite economical but very decorative feature to a garden, whatever its size, is a pergola. This also can be easily and cheaply formed—

when the men are on the job. From twelve to eighteen simple ferro-concrete piers with old timbers laid across them, or branches lopped from any trees that may have to be felled for the house-building, are all that is necessary. The pergola should cover the main path, or it might run close to and parallel with the house, or form a pleasing break between the pleasure and the vegetable gardens. Yet another small but effective feature in garden construction is the seat. This can easily be formed in the wall of the terrace, or that at the end of the garden or in the bank separating the two divisions. For small property I do not recommend "garden ornaments"; one good piece, however, may well be placed in the centre of a sunk garden; sundials are out of the question, of course, but a single flower vase or cement plant tub (they can be bought as low as 17s. 6d. each) on a concrete pedestal, would serve to break the monotony and enliven the dulness of an ordinary back garden plot.

Whatever the means employed, however, for constructing or adding decorative features to a small garden, I do plead that gardens be formed, even to the smallest class of dwellings and also that the garden be planned before the house and created during its building. Obviously, time and labour are saved; costs of materials and overhead charges are reduced, and the letting or selling value of the house so provided with a well planned garden is more than proportionately raised. I trust I shall not be accused of setting "the cart before the horse," for on the contrary, I maintain that it is good, sound policy to prepare the plans for the whole before planning the part, even the major part of house property. Naturally, the same principles apply to houses standing in their own grounds or to villas in the country, but my contention is that they are quite as requisite and desirable for small houses and that in the case of the latter, their application "pays" everyone concerned—the landlord, the house-owner, the occupant and the builder. E. W. RICHARDSON.

EUCRYPHIA PINNATIFOLIA

ALTHOUGH discovered as long ago as 1845 and introduced in 1859, this beautiful Chilean shrub (sometimes a small tree) is far from common in gardens. Near London it is perfectly hardy; it has been known to survive 32° of frost. Yet it is evident that its cultivation is not thoroughly understood, or we should see more of it. Experience shows that it needs, more than anything else, cool, moist conditions at the root. At Kew, grown as an ordinary isolated lawn shrub, it has never lived long, owing, probably, to its inability to withstand the fierce spells of heat which, if often short, are not infrequent in the Thames Valley. The best success with it has been obtained by planting it in association with *Erica mediterranea*. The Heath keeps the ground permanently shaded and cool, and it is not greedy at the roots. At planting-time a few barrow-loads of peat and leaf-soil should be put about the roots. The shrub is evergreen, its leaves being made up of three or five lustrous dark green leaflets. The flowers are 2½ ins across, a conspicuous feature being the large bunch of stamens with yellow anthers. Opening as they do when the flowering season of trees and shrubs in general is waning, they make the shrub particularly attractive. This shrub is not common in gardens, no doubt due to the fact that it is not easy to propagate or transplant. However, seeds are produced now in this country, so this should facilitate propagation. It has in the past only been increased by layering.

CORRESPONDENCE

TRANSPLANTING TIMES.

REFERRING to the enquiry on the above subject in *THE GARDEN* of March 25, page 143, it is an undoubted fact that the end of April or beginning of May are favourable times for planting either Yews or Hollies, or, indeed, many other evergreens. Many good judges prefer to wait even a month later, and on heavy, difficult soils I know of a very successful planter of Yew and Holly hedges who preferred the middle of June. But I may say in my experience that, provided the plants are *well rooted*, either Yews or Hollies and most other evergreens can be planted with perfect safety from September to June, always provided the soil is fit to work. I have been most successful in autumn planting, and there again one must have moisture either natural or applied, and with the ground warm and the plant in an active condition, it will make young roots in a very short time. During the war, when every day counted, I moved some three acres of various evergreens, commencing on the day after August Bank Holiday, and not a single loss was incurred. Among the plants so handled were Thuyas, Cypresses, Yews, Hollies, Spruce and other Firs. Some plants are difficult to transplant when in a dormant condition; for example, *Berberis Darwinii*. I have seen the roots of this plant rot away in cold, wet soils. The best time to move it is either April or October. I believe it to be true that if you have to move any evergreen which is badly rooted, or not specially prepared for moving, that it is best to plant when signs of growth and general vitality are evident, and that is either early autumn or spring. Properly grown nursery plants may be handled, as I have already said, from September to June. Naturally, care must be taken to see that the plants do not lack moisture until re-established.—F. GOMER WATERER.

PRUNING FRUIT TREES.

A MAN in business has very little leisure in these days for writing to the papers and none at all for controversy. My only reason for writing to *THE GARDEN* was to enter my protest against the close pruning of Apple trees, which although established, have no bloom buds formed on the spurs, and having done so, to let the matter drop; however, as Mr. W. Mason (page 120) asks for further information, I will do my best to give it. In the first place there seems to be considerable confusion in the terms bush and pyramid trees. With most people the terms are interchangeable, while others call a practically unpruned tree, growing as it likes, a bush, and a formed and pruned tree a pyramid, to distinguish it from a standard. I cannot now refer to the number of *THE GARDEN* in which my letter appeared, but if I used the word pyramid it was because there was an illustration of well pruned trees to which I referred and which were called pyramids, and if my having done this has caused any confusion in the mind of your readers I offer them my apologies, for it was not my intention to recommend the pyramid form.

When I learned to prune fruit trees at the School of Horticulture, Ghent, in 1870, there were in Mr. Van Houtte's gardens some lovely pyramid Pear trees trained with four or six wings, each wing perfectly flat and radiating from the centre stem like the spokes of a wheel so that one could get in to prune with ease and all the wood was exposed to sunlight and air. This I should call the finest form of pyramid. Then we have such trees as were illustrated in the recent issue of *THE GARDEN*, and lastly, we have the all-too-common sort of sugar-loaf tree, pretty well solid with branches (owing to close pruning) and a fitting

site for a blackbird's nest. I need scarcely say that the first and last forms are not in any way suited to commercial fruit-growing; the first being much too expensive to form and keep up, and the last unprofitable. The fruit-grower has to shape and prune his trees somewhat in accordance with their natural habits, aiming at the form illustrated, upright growers having their branches thinned out so as to admit light and air to the centre of the tree, and those of a more spreading habit receiving similar treatment, but with the result that they are not the same shape, and the two types should be planted alternately so as to economise space. Each branch of the tree is treated as a single cordon.

The distance to plant apart varies with the soil and also the variety planted. I have seen Bramley's on paradise stock in Norfolk planted 24 ft. apart and grown so closely to each other as to make it very difficult to walk between and quite out of the question to get any kind of cultivator among them, but on ordinary good soil 18 ft. will suffice, especially if the alternate planting of an upright and spreading tree is adopted; on light land 12 ft. to 15 ft. is enough. The best upright-growing Apples are Annie Elizabeth, Barnack Beauty, Ellison's Orange, Hector Macdonald, Herring's Seedling, Melrose White and Worcester Pearmain.—A. H. PEARSON.

V.M.H. AWARDS.

I HAVE been connected with horticulture for the major part of half a century and have personally known most of the eminent men connected with it, and am not surprised to find that dissatisfaction exists concerning the bestowal of this distinction. At the most, the V.M.H. is merely a society's medal, awarded by a little circle, whose acquaintance with horticulture must necessarily be limited and in a great measure limited to that part of it which immediately concerns the R.H.S. What the determining factors are that govern the Council's decisions in awarding the medal to certain persons no one outside that body can tell. But, Mr. Editor, without mentioning names, for there is no need in discussing a principle to cause pain to any one of the sixty-three elect there is one person holding the V.M.H. whom I have never seen, never heard mentioned by anybody in the horticultural world and have never known what he did or seen his name in print except in the list of V.M.H. holders. What has this gentleman, who is absolutely unknown to thousands of gardeners and horticulturists, done that he should have been deemed worthy of this special distinction? There is a great deal of horticulture outside the R.H.S., perhaps infinitely more than the Council in its corporate capacity has any idea of, but those who run the machine, as you pointedly put it, seem to be especially favoured. "Scrutator" (page 132), says, "it is only fair to point out that the Council are not unduly generous to themselves." That is, beyond any question, purely a matter of opinion, considering that practically one-fourth of the total number of V.M.H.'s. or to be precise, fifteen of

them, have been bestowed upon members of the Council and officers, as appears by the title page to this year's List of Fellows. Mr. John Fraser is not "a Show Bird" occupying some prominent honorary position, but a diligent, painstaking journalistic worker of many years experience. He has rendered valuable service to horticulture in a way that has seldom been recognised by the R.H.S. and therefore his present appointment has been received by his many friends and acquaintances with the utmost satisfaction.—SENEX.

A DISTINCT ALMOND AND THE "BLACK APRICOT."

I SEND you a photograph of a very fine and distinct Almond from one of two large trees in Mr. H. E. Richardson's garden, Shankill County,

A BEAUTIFUL CRIMPED-PETALLED PALE-FLOWERED VARIETY OF THE ALMOND.

Dublin. The flowers are very open, much larger and of better substance than the ordinary Almond, pale pink inside the edges, wavy, and of a lovely shell-pink shade. They measure 1½ ins. across. The branch from which the spurs photographed were taken has been cut exactly a fortnight, and is still fresh, unlike most Almonds the blossoms of which drop quickly when cut. These fine trees are probably about thirty-five or forty years old. Unfortunately for envious beholders, they cover every spur with flower buds and make very few free shoots suitable for propagation.

When I opened my March 4th copy of *THE GARDEN* and read the verse, "March Morning":

"Four corners to my garden span,
Four almond trees in bloom.
What should I ask of God or Man?
My heart has no more room!"

I saw plainly that Miss Friedlaender has never seen *Prunus dasycarpa* or she would expand her heart to take it in. Of all the white-flowered *Prunus* I say confidently there is none to approach or excel this beautiful tree. It is commonly called in nurseries, I am told, the Black Apricot, but unfortunately, it does not seem common in gardens or nurseries. The tree here came from M. Simon Louis of Metz. It is a middle-sized tree, and bends gracefully, showing smooth, slender branches. The leaves, which have not yet appeared this season, are oval and rough. The sepals in bud state are reddish, the flowers, borne on short stalks, when fully open are 1½ ins. across. The great merit and beauty of *Prunus dasycarpa* are its lasting qualities and the substance and purity of its petals. A few branches cut when in bud placed in water give great pleasure, watching it opening from the bright reddish sepals of the solid white buds to the fully

expanded flower. Its quality and texture in comparison with *Prunus communis* is as that of the best Irish poplin to the thinnest of pongée silk. The tree in this garden has not borne fruit which is described as being dark purple with a tawny austere flesh. Its native country is unknown.—W. PHYLIS MOORE, *Glascow*.

[Some sprays in the bud state which Lady Moore sent for the Editor's table, unfolded rapidly when placed in water and were almost all expanded the following morning. The blossom certainly deserves her encomiums.—ED.]

THE MAIDEN PINK.

THE species of *Dianthus* are so numerous and the botanical differences so fine in some cases that their distinctions often are not readily discernible. On page 133, under the heading of "An Easy and Fragrant Plant," a question is asked as to the difference between the Maiden Pink (*Dianthus deltoides*) and *D. graniticus*. The first named has stems with short branches near the top, each ending in a single flower, rarely two, and they (the flowers) always have a short stalk above the uppermost pair of leaves. The five petals are rather widely separated, never touching one another by their edges, and have a transverse purple line at the base, with some purple spots on a white ground above this. *D. graniticus* has never more than one or two flowers on a stem, and both are surrounded by the uppermost pair of leaves, without a stalk. The flowers are smaller, the petals touch one another by their edges and there are no spots. These are the broad distinctions, but there are others, for the two are widely separated botanically and belong to different sections. When both are growing freely it will be seen that *D. deltoides* has branching stems, which *D. graniticus* never has. They could only be connected by hybridisation.—J. F.

THE HARDY CITRUS.

I WAS much interested in the article on Citranges in Ireland which appeared in your issue of March 4. Although the Citrange has a disagreeable flavour when eaten raw, I would suggest that if treated like its relatives, the Citron and the Kumquat, and placed in brine for a week or two, then boiled and treated with syrup, it would form a delicious preserve. *C. trifoliata* has, I believe, proved of greater service as a stock to graft on than for hybridisation. I wish to draw attention to the fact that *C. trifoliata* has proved perfectly hardy in the Eastern Counties. A tree about 12ft. in height, which grows in the open at the Botanic Garden, Cambridge, withstood 30° of frost last year, and in the following spring it was covered with white fragrant blossom, and the abundant fruit which followed ripened well. I believe that if its hardy constitution and decorative appearance were more generally known it would be far more often seen in our English gardens. At any rate, there is no need for it to be confined to Ireland or our Western seaboard when it may be seen growing in chilly Cambridgeshire to perfection.—H. H. WARNER, *East Herts.*

Citrus trifoliata is probably harder than the Laurel, but its lack of popularity seems not difficult of explanation. It is due to the unfortunate fact that, in ordinary situations, it seldom flowers, and yet more seldom fruits.—ED.]

ALPINES AND ELEVATION.

AN interesting question is raised by H. Stuart Thompson on page 132 when speaking of alpenes which he has found at varying elevations on different ranges of mountains. The question is that some plants ascend to greater elevations on the high Swiss Alps than they do on lower

ranges of more southern mountains, and that they descend to lower elevations on the latter. The suggestion that the ground of the high Alps is warmer than the air is no doubt one reason. Another may be that the ground of the high Alps is covered for a greater part of the year with snow than is the case on more southern ranges of mountains. I would suggest a third reason, namely, that many alpenes in Britain do not ascend to the top of the mountains, but choose a place lower down where they can get a more continuous supply of moisture and, at the same time, get shelter from the hurricanes of wind which frequently prevail. This is particularly noticeable in the case of such alpine Willows as *Salix lanata*, *S. Myrsinites* and *S. Lapponum*. These may often be near the edges of perpendicular rocks or otherwise, but always where they get a considerable drainage from higher ground. The driest situation where I have found *Saxifraga oppositifolia* was on the peak of the Brecknock Beacons at an altitude of 2,910ft. On dripping or moist rocks of the old red sandstone on the shores of the Moray Firth I have seen it at 50ft. above the sea and lower. In the shelter of rocks by the crater-like top of Ben Lawers it grows and flowers freely early in June. This mountain is 3,984ft. high. *Sedum roseum* is abundant below the tops of many of the Breadalbane Mountains, but is plentiful near sea level on the Moray Firth. *Silene maritima* and *Armeria maritima* behave in the same way.—HORTULANUS.

GARDENING PROVERBS.

I AM sending you a gardener's alphabet of proverbs, from a page of grandfather's gardening notes.—L. E. T.

Autumn-sown annuals flower soonest and strongest.

What you sow in spring, sow often and thin.

Bulbs bought early are best chosen. If you wish your Tulips to wake up gay, they must be all be in bed by Lord Mayor's Day.

"Cut my leaves this year, and you won't cut my flowers next year," said the Daffodil to Tabitha Tidy. Cut a Rose for your neighbour, and it will tell two buds to blossom for you.

Don't let me forget to pray for travellers when I thank Heaven I'm content to stay in my own garden. It is furnished from the ends of the earth.

Enough comes out of anybody's old garden in autumn to stock a new one for somebody else.

But you want sympathy on one side, and sense on the other, and they are rarer than most perennials.

Flowers are like gentlemen—"Best everywhere."

Give Mother Earth plenty of food and she'll give you plenty of flowers.

He who can keep what he gets, and multiply what he has got, should always buy the best kinds; and he who can do neither should buy none.

If nothing else accounts for it, ten to one there's a worm in the pot.

Jobbing gardeners are sometimes neat, and if they leave their rubbish behind them, the Hepaticas may turn up again.

Known sorts before new sorts, if your list has limits.

Leave a bit behind you—for conscience's sake—if it's only *Polypodium vulgare*.

Mischief shows in the leaves, but lies at the root.

North borders are warmest in winter.

Old women's window-plants have guardian angels.

Pussy-cats have nine lives and some pot-plants have more; but both do die of neglect.

Quant, gay, sweet, and good for nos-gays, is good enough for my garden.

Rubbish is rubbish when it lies about—compost when it's all of a heap—and food for flowers when it's dug in.

Sow thick, and you'll have to thin; but sow Peas as thick as you please.

Tree-leaves in the garden, and tea-leaves in the parlour, are good for mulching.

"Useful if ugly," as the toad said to the Lily when he ate the grubs.

Very little will keep Jack Frost out—before he gets in.

Water your Rose with the slop-pail when it's in bud, and you'll be asked the name of it when it's in flower.

Xeranthemum, Rhodanthe, Helichrysum, white, yellow, purple and red. Grow us, cut us, and hang us with drooping head. Good Christians all, find a nook for us, for we bloom for the Church and the Dead.

You may find more heart's-ease in your garden than grows in the Pansy-bed.

Zinnia elegans flore-pleno is a showy annual, and there's a coloured picture in the catalogue, but—like many other portraits—it's a favourable likeness.

[The above shows that there were good gardeners long ago, though one takes grave exception to "Sow Peas as thick as you please."—ED.]

CLUB ROOT IN CABBAGES.

IS it possible still to procure "Seride," the preparation which some seven years ago was recommended in THE GARDEN as a preventive against "Club"? I found this entirely satisfactory and used to procure it from a Watford chemist, but am now unable to get into communication with him. If any reader can assist me I shall be most grateful.—C.

A LITTLE-GROWN PLANT.

I SAW a clump of a charming plant in flower last September in Mr. Samuel's garden at Wrexham, where I had been taken by a friend to see his one year old Delphiniums in bloom. He told me its name was *Bidens dahlioides*, so when I got home I tried to look it up in my gardening books; but one after the other they were drawn blank until I came to Bailey's big American Dictionary, and there it was just mentioned as a sort of footnote at the end of the article "Bidens," which means that not very much is known about it. In despair I took "My Garden in Summer" down. Of course, I should have done so before. What books those three volumes, "My Garden in Spring," "My Garden in Summer" and "My Garden in Autumn," are! They are vade-mecums for nearly everything that is good for garden decoration in the hardy plant line. Mr. Bowles, their author, is a very fine flower painter, and he has an eye for floral arrangements indoors. To this, possibly, we owe the mention of *Bidens dahlioides*. He says it is very pretty, particularly the white variety. Mr. Samuel, at all events, prizes it highly as a cut flower, especially when mixed with *Gypsophila*. Incidentally, I have found in my search for *dahlioides* that the genus *Bidens* is one of the happy dumping grounds of the botanical classificationalist; or perhaps it should be called an eclectic conglomeration of species of pronounced cuckoo-like propensities. That there is some ground for these animadversions may be gleaned from the pages of a modern gardening dictionary, wherein we find that one species once a *Bidens* is now a *Dahlia*, and that two which were once upon a time, the one a *Cosmos* and the other a *Coreopsis*, are now *Bidenses*. One can see in a dim way the method of these changes. The large, pinnate bushy foliage suggests a *Dahlia*; the thin, wiry stems a *Coreopsis* and the blush flowers a *Cosmos*. *Bidens dahlioides* is an excellent plant to grow for cutting in September.—JOSEPH JACOB.

BORDER CARNATIONS

You MUST plant now if you are to get the best results this year. We have superb stocks of all the leading varieties for immediate delivery ex 3 1/2 in. pots. The undermentioned collections are available at—

CELEBRATED KING'S NORTON LOAM

for Roses, Carnations, Chrysanthemums, Tomatoes, etc. Full fibre, top spit, for immediate use or stacking. ROLLED TURF, Lump and Ground LIME, Derbyshire DOLOMITE, Matlock Spa TUFF, ROCKERY STONE, Yorkshire CRAZY FLAGS. Rock Gardens laid out. Crazy Paving laid. Experienced men.

E. R. GELL, Ltd., Merchants & Contractors,
KING'S NORTON.

HORTA

Fertilisers & Insecticides.

HAREN (Belgium).

High Pressure Liquid Sprayers,

'Le FORTUNE HORTA'

$\frac{1}{2}$ gallon hand sprayer, 4 gallons
sprayer to carry on back, 17 gallons
sprayer on wheeling carrier.

May be used with extension lance.

Practical — Strong — Cheap.

Price List sent free of charge.

34th SEASON.

MRS. PYM'S FAMOUS PLANTS

GOOD AND CHEAP.

SPECIAL OFFER of good, strong, sturdy plants. Should be planted now for success: Half same rate. All post free or carriage paid, passenger train. Cash with order. Catalogue free.

4d. extra for orders under 3s.

Strong vegetable plants, wintered in open: Cabbage, Leeks, Tripoli Onions, Coleworts, Pickling Cabbage, Cos and Cabbage Lettuce, Perpetua Spinach, 100, 1/9. Rhubarb, best named, red, 6, 1/6. Sage, Thyme, Mint, Marjoram, 6, 1/6. Parsley, best curled, 12, 1/4. Cauliflower, strong, transplanted, wintered in frames, 20, 1/6; 50, 3/-. Asparagus, colossal and giant, strong 2 year old roots, 30, 4/-; 100, 7/6.

HARDY PERENNIALS, very strong, transplanted, to flower this year. Best strains procurable. Achillea, Perry's double white, 3, 1/6. Aconitum, handsome new large flowering named, 3, 1/6. Aster alpinus, rare lovely rockery plants, 2, 1/4. Agrostemma, crimson, 6, 1/6. Alstromeria, Peruvian Flame Flower, 2, 1/4. Alyssum, gold dust, 6, 1/6. Alpine Wallflowers, 20, 1/6. Alpine Pinks, 12, 1/9. Anchusa italica, Dropmore, lovely blue, 6, 1/9; Anchusa angustifolia, true deep blue, 6, 1/6. Anemone japonica, pink or white, 2, 1/4. Anemone pulsatilla, a most beautiful spring flower ring hardy perennial followed by handsome fruit, 2, 1/4. Anthemis montana, 6, 1/9. Aquilegia, Kelway's hybrids, 6, 1/4. Arabis, double white, 6, 1/6. Aubrietia, rich purple, 6, 1/6. Auriculas, lovely alpine varieties, 4, 1/6. Antirrhinum, bushy plants, lovely new colours, 6, 1/4. Brompton Stocks, large, year old, 6, 1/6. Christmas Roses, large crowns, 1/4 each. Campanulas, blue or white dwarf or tall, 3, 1/4. Campanula pyramidalis, 2 year old, 3, 1/6. Canterbury Bells, single, blue, pink, mauve, white, or Dean's grand hybrids, 12, 1/9; double, 6, 1/6. Candytuft, perennial, 3, 1/6. Carnations, good border, 6, 1/6; separate colours, white, yellow, crimson, scarlet, 6, 1/9; Grenadin, lovely double scarlet, 6, 1/9. Centaurea montana, blue, white or rosy mauve, 6, 1/6. Chrysanthemums, strong rooted cuttings, best early, mid and late, all colours, separate or mixed, 6, 1/6. Cerastium, 12, 1/9. Cistus (Rock Rose), 6, 1/9. Coreopsis grandiflora, 6, 1/4. Cornflowers, Kelway's blue, 12, 1/6. Daisies, new enormous double blooms, red or white, splendid for bedding, 12, 1/4; mixed, 20, 1/6. Delphiniums, best named, large 2 year old, 2, 1/9. Delphiniums, grand, large flowering hybrids, light or dark blue, year old plants, 3, 1/6. Dianthus, Kelway's lovely double or single, 12, 1/6. Dianthus, creeping, bright pink, 6, 1/4. Delytrea, Bleeding Heart, large roots, 1, 1/4. Erigeron (Stemless), mauve Marguerite, 4, 1/6. Erigeron, new Quaker's, 3, 1/6. Erysimum, Golden Gem, 20, 1/6. Forget-me-nots, best dwarf blue, perennial varieties, 12, 1/4. Funkia subcordata grandiflora alba (Corn Lily), most lovely, pure white, exquisitely fragrant flowering, prized for cutting, very handsome, large glaucous green leaves, 3, 1/6. Gaillardia grandiflora, 6, 1/4. Galega (Goat's Rue), 6, 1/6. Gladiolus, best large flowering, 12, 1/9. Geum Mrs. Bradshaw, large double scarlet, 2, 1/6. Geum, scarlet, 4, 1/4. Galtonia, hardy white Lily, long stout stems covered with waxy bells, 2, 1/4. Gypsophila paniculata, 6, 1/6. Gypsophila, dwarf, 12, 1/9. Heuchera, scarlet, 4, 1/4. Hollyhocks, lovely colours, single, 6, 1/6; double, 4, 1/6. Honesty, crimson and white, 6, 1/4. Iceland Poppies, Excel-hor strain, 6, 1/4. Iris germanica, separate colours, mauve, white, blue, purple, yellow, 3, 1/6. Iris, large flag, splendid colours, 6, 1/6. Kniphofia, handsome Torch Lily, 3, 1/6. Linum (Blue Flax), 12, 1/9. Lily of the Valley, giant variety, soon flower, 6, 1/6. Hardy Lilies, large, orange red and tawny, 3, 1/6. Linaria dalmatica, 6, 1/6. Lobelia cardinalis, 4, 1/6. Lupinus polyphyllus, pink, white, blue, 6, 1/6; mixed, 12, 1/9. Lupin, true, yellow or white, 3, 1/6. Lychnis, scarlet chalcidonica or Salmon Queen, 6, 1/6. Malva, bright pink, 6, 1/6. Monarda (Bergamot), Cambridge scarlet, 2, 1/4. Montbretias, new varieties, 12, 1/6. Pansies, best large flowering, and separate colours for bedding, 12, 1/6. Papaver piosum, rich orange blooms, 6, 1/6. Phlox, best, large flowering, mixed, 4, 1/6. Phlox, best large flowering, all colours, 3, 1/6. Paeonies, separate colours, 2, 1/6. Paeonies, mixed, 3, 1/6. Poppy, Oriental Queen, enormous blooms, 6, 1/6. Physalis (Giant Cape Gooseberry), 6, 1/6. Pinks, coloured garden, 12, 1/9. Pinks, double white, 6, 1/6. Potentilla, double crimson, 6, 1/6. Primulas, hardy assorted, for succession of bloom, 6, 1/6. Pentstemon, large bushy scarlet, Southgate Gem and grand Excel-hor strain, 6, 1/9; smaller good plants, 6, 1/4. Pyrethrum, Kelway's, 6, 1/6. Pyrethrum James Kelway, large scarlet, 2, 1/4. Pyrethrum, double red, white, pink, 3, 1/6. Rose Campion, bright crimson, 6, 1/4.

Rudbeckia speciosa, 3, 1/6. Saponaria, pink rockery, 6. Scabious, Sweet, 12, 1/9. Scabious caucasica, large mass 1 year plants, 3, 1/6. Silene compacta, pink, 15, 1/6. Star (Lamb's Wood), 6, 1/4. Star of Bethlehem, 6, 1/6. Star (Sea Lavender), 3, 1/6. Sweet Rocket, 12, 1/6. Sweet William, double and single mixed, lovely colours, 12. Sweet William, lovely scarlet, pink, and Crimson Bee, 6, 1/4. Thistle Queen of Scots, 3, 1/6. Thalictrum (the Maidenhair), 4, 1/6. Tritoma (Red-hot Poker), 3. Tussilago (hardy winter Heliotrope), 3, 1/6. Verbascum tall, 6, 1/6. Valerian, crimson, 6, 1/6. Veronica, 1/4. Viola, separate colours, for bedding, and good mix, 12, 1/6. Viola cornuta, mauve, purple, blue and white, 12. Viola masses of bloom for rockery, etc., 12, 1/9. Violas, strong root cuttings, Maggie Mott, best mauve; King Cup, best yellow; White Swan, best white, 6, 1/6. Sunflowers, new red, 3. Aster, Michaelmas Daisy, good named sorts, 3, 1/6. Achillea new very bright Crimson Queen, 3, 1/6. Antirrhinum strong autumn sown (not transplanted), 12, 1/6. Centaurea dealbata, lovely large fringed pink flowers, pretty self foliage, 3, 1/6. Chinese Pinks, very showy, 6, 1/6. Campanula macrantha, tall, large mauve blooms, 3, 1/6. Chelone barb coral red lobster flower, 3, 1/6. Crucianella, lovely for rock deep heads of pink bloom, 6, 1/6. Dianthus, rock, dwarf lovely colours for rockery, 6, 1/6. Hypericum (St. John Wort or Rose of Sharon), large yellow blooms, evergreen gl foliage, 4, 1/6. Incarvillea Delavayi grandiflora, beautiful large Gloxinia-like blooms, handsome foliage, 3, 1/6. Iris glandulosa, large golden yellow flowers, bold and handsome, 3, 1/6. Lavender bushes, fragrant old English, 3. Japanese Pinks, very pretty colours, 6, 1/4. Pyrethrum Queen Mary, large double rose pink, 2, 1/4. Oriental Poppy very large salmon blooms, large plants, 3, 1/6. Shiu Poppies, beautiful art shades, 6, 1/4. Pansy Coquette Poisey, beautiful pale mauve, for bedding, 12, 1/10. following Primulas are quite hardy, thrive best in damp situations, and do well in pots: Primula japonica, 4, 1/6. cortusoides, bright rosy purple, 4, 1/6. P. Bulleya beautiful shades, 3, 1/6. P. pulverulenta, rich colours, 4. P. denticulata cashmirena, large heads, light purple, 3. Rudbeckia Golden Ball, double, 3, 1/6. Perennial Sunflower Miss Moll's, etc., 6, 1/6. Saxifraga, mossy, white, pink, crimson, 4, 1/4. Rock Rosee, trails of lovely coloured flower rockery gem, 6, 1/9. Cheiranthus, Siberian Wallflower masses of bloom all summer, 20, 1/6.

Strong transplanted plants for cool houses: Agapanthus, large blue African Lily, year old plants, 3, 1/4. Agath (blue Marguerite), 4, 1/4. Asparagus Fern, erect or trailing, 4, 1/4. Begonias, scarlet, crimson or Salmon Queen, evergreen, perpetual flowering, 6, 1/6. Auriculas, grand large flowering, show, 4, 1/6. Cannas, Crozy's splendid hybrid large 2 year old, 3, 1/6; 1 year, 4, 1/4. Cinerarias, exhibit and stella, 6, 1/4. Eucalyptus, 4, 1/4. Francoa (Brit Wreath), 6, 1/6. Gloxinias, grand, large flowering, narrow, 2, 1/4. Heliotrope, very large heads, fragrant blue, 4, 1/4. Lobelia cardinalis Queen Victoria, 4, 1/4. Nicotiana white or crimson Tobacco, 4, 1/4. Primula malacoides (rock blue), 6, 1/6. Primula obconica, new, giant, lovely colour, 4, 1/4. Rehmnia, pink trumpet, 3, 1/6. Salvia, Scarlet, Zurich, 4, 1/4. Salvia, scarlet coccinea, 6, 1/4. Saxifraga Mother of Thousands, trailing, 4, 1/4. Streptocarpus, love Cape Primrose, large blooms, lovely colours, 4, 1/4. Arisaema (Fit Palm), 2, 1/4. Celcia critica, pretty spikes of yellow and mauve flowers, 4, 1/4. Cyclamen, choice new sorts, 3, 1/6. Fuchsias, choice varieties, 3, 1/6. Marguerites, large yellow and Covent Garden White, 4, 1/4. Smilax, trailing, 3, 1/6. Cordyline Dracaena indivisa Vetchii, handsome hardy plant strong 3 year old, about 9ins., 2, 1/6. Tomatoes, strong transplanted, best sorts, 6, 1/6.

Hardy Climbers. Ampelopsis Vitellid, self-clinging Virginia creeper, large roots, several trunks, 2/6 each. Clematis calyba (Traveller's Joy), rapid grower, large roots, 2/- each. Calystegia, double pink, Morning Glory, rapid climber, 3 root 1/6. Tropaeolum speciosum, scarlet, 2, 1/6; Apios tuber rooted Wisteria (not sinensis), 2, 1/4. Passiflora Flow hardy, blue and white, 2, 1/6. Peas, everlasting, white, pink, mixed, large roots, 3, 1/6. Eccromocarpus, truss orange flowers, 2, 1/4.

MRS. PYM, F.R.H.S.,
10, VINE HOUSE, WOODSTON, PETERBOROUGH

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Asparagus.—Where it was decided to plant new beds, the preparation of them will have been completed as advised in the "Gardening of the Week" of February 4th. Select now the first favourable opportunity when the soil is in good working condition to get the planting done. If the beds are made from 3ft to 4ft wide, it will allow of three rows of plants a foot apart; this size is a very convenient one for gathering from. Among several good varieties to choose from, Giant French and Conover's Colossal may be relied upon. Roots two years old will probably be the best for planting for general purposes, and it is most essential that Asparagus roots be exposed as little as possible to the air while planting is in progress.

Potatoes.—The planting of the earlier varieties should be now completed as soon as it can be arranged, allowing a distance of from 20ins to 30ins. between the rows according to the vigour of the variety. Wherever the soil is at all heavy or cold, line the channels or holes with decayed leaf soil before placing the sets therein. If more convenient to arrange the planting of the mid-season and late varieties now there is no reason why this should not be done, but allow more room between the rows.

Peas and Broad Beans.—The quantities required to be sown at intervals of every few weeks will depend upon the demands of the establishment. It is essential for a sowing of Peas to be made every three weeks to keep up a continuous supply. Both Peas and Beans delight in a good depth of well worked soil, but give the site which has the strongest soil to the Beans. Peas should always be staked when a few inches high.

Marrow Beds.—Where such material as leaves and stable litter can be spared, a good heap should now be got together in readiness for these plants. It is a good plan to sow some seeds in pots indoors and grow them along, planting out when large enough and well hardened off, and also to sow direct into positions on the bed, placing two or three seeds under a hand light. Where space is limited and it is inconvenient to arrange for the trailing varieties, the bush varieties give excellent results.

Seeds of Brassicas to be got in now include a further sowing of Cauliflower, Cabbage, Broccoli, more Brussels, also an early sowing of Kale and Savoys. Sow thinly and take steps to protect seedlings from birds as soon as they are through the soil. Plants from earlier sowings of several of the above should be pricked off and planted out as they become large enough to be handled.

The Flower Garden.

Spring-flowering Plants are benefited by a shallow stirring of the soil and this also checks the seedling weeds. Attend at the same time, if necessary, to the edges of the beds. Where Hyacinths are used for bedding purposes such staking as is necessary must be seen to. Tall growing Tulips, too, in exposed beds may need support; small green stakes are the most inconspicuous to use for this purpose.

Sweet Peas.—Should a further sowing be necessary it should be done at once, and it will repay always to give the plants a rich and well worked soil.

Dahlias.—Any increase of stock required may be readily obtained either by cuttings or division of the roots. For the former method the old plants should be introduced into medium heat and sprayed occasionally when plenty of young growths will soon be available. Division of the roots may be carried out either before the plants recommence their growth or when they have just started.

The Hardy Fruit Garden.

Strawberries.—If a light forking or hoeing has not yet been given it should be done, at the same time removing any decayed leaves. Where, on heavy land, owing to the constant rain, any intended spring bed has not been planted, it is not too late to carry the work out now. If the alpine section are grown, a bed planted now will, with careful attention, give quite good results towards the latter end of the summer. Should a further increase of these be required it is easily obtained from seed, a method which is preferred by some growers. Sow in boxes of light soil and as soon as the seedlings are large enough, prick them out a few inches apart on a shady border until ready to plant in their permanent quarters. For this section put

the plants a foot apart in double rows, allowing 15ins. between the rows.

Fruits Under Glass.

Disbudding Peaches and Nectarines.—This work should be commenced as soon as the fruits are nicely set and the young shoots have begun to show increased activity. The operation was described and illustrated in THE GARDEN for March 4. The disbudding should be done on different occasions, thus minimising the danger of any sudden check by the removal of too many growths at once. First of all remove those growths which are badly placed and those that are entirely on the underside of the branches. The two essential growths to take care of are the ones chosen eventually to form the basal growth and the leader. The former, furnishing us with our next year's fruiting wood, is sometimes even more important to us than a leader, for the general use of a leader is to carry the sap up to nourish any fruits there may be on the branch, and it sometimes happens that it may be more beneficial to the tree if it is cut back quite early in the season to the growth which has been retained for next year's fruiting.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Potatoes.—Proceed with the planting of second-early Potatoes. The ground should be well worked and generously manured beforehand. Exercise care when planting, so that the sprouts are not damaged in any way. Early sorts growing in frames should be allowed abundance of ventilation during fine weather. Apply water regularly, so that the tubers may be induced to swell freely.

French Beans.—Fortnightly sowings of these should be made indoors, so that regular supplies may be maintained. Growth is now quicker and stronger, so better results may be expected from this time onwards. A mixture of three parts loam to one part of leaf-mould suits them well. Syringe the foliage twice daily when the weather is fine. Close the pit early in the afternoon, so that as much sun-heat as possible may be retained.

Saladings.—Prick out early sowings of Lettuce into frames and keep growing freely. Sow Radish seed at frequent intervals, encouraging a quick and regular growth, so that crisp, succulent roots may be produced. Mustard and Cress is still better sown in boxes under glass.

Peas.—Plants that have been brought forward under glass should now be transferred to their final quarters. Care must be taken that the roots are not unduly damaged during the process. Stake the young plants with small feathery Spruce twigs, as these not only act as a support, but protect the tender growths from the cold winds so prevalent in the North during early April.

Planting Asparagus Beds.—Where the planting of new beds is contemplated, the work should be carried out as speedily as possible. Provided the soil has been well prepared during the winter months, the site should only now require to be well forked over and a sprinkling of agricultural salt and soot added. Opinions differ regarding the width of the beds, but that which conveniently holds two rows of plants is generally admitted to be the most suitable. Where the intention is to form new beds by sowing seed, this work may also be carried out now. Sow in rows 18ins. apart, and thin out the seedlings to 15ins. apart in the rows.

Fruit Under Glass.

Peaches.—Trees carrying heavy crops will benefit by an occasional watering with weak liquid manure, or a discreet dressing of an approved chemical manure, well watered into the border. Thin out the fruits of early crops when they are about the size of nuts. Pots of late varieties now flowering in the orchard house should still be assisted by hand fertilisation.

Late Vines.—Late Vines will now be considerably advanced, so that all superfluous shoots should be rubbed off without delay. Guard against sudden bursts of sun-shine, as the tender growths of some varieties scorch readily if ventilation is not carefully attended to.

Strawberries in Pots.—Early batches with rapidly swelling fruit should now be assisted with copious waterings of liquid manure. Syringe the foliage freely during fine weather, so that red

spider may be kept in check. As soon as the fruit shows a tendency towards ripening, remove the plants to cooler quarters, as this treatment materially assists in giving the fruit a more piquant flavour.

The Hardy Fruit Garden.

Mulching Newly-planted Fruit Trees.—To prevent newly-planted fruit trees suffering from drought, more especially on very light or gravelly soils, they should be given a generous mulch of well decayed farmyard manure. This helps to keep the root-run cool and checks evaporation.

Strawberries.—In making new plantations of these it is essential that the ground be in good heart, and provided that the bed has been well prepared during the autumn, it will now break down freely, and the young plants should have little difficulty in establishing themselves. Runners that were planted in the reserve border with a view to spring planting are now starting into growth, so should be lifted carefully and planted on the new site, in rows 2ft. apart and 15ins. apart in the row. Established beds should have the Dutch hoe run through between the rows, so that the hard crust may be broken, thus allowing air and warmth to be more readily admitted; weeds are also checked, and root action quickened.

The Flower Garden.

Biennials, such as Sweet Williams, Canterbury Bells and Agrostemmas, should now be transferred to their flowering quarters. Other hardy plants, such as Hollyhocks and Geums, which have been growing in the nursery garden with a view to the embellishment of the hardy border, should also be transplanted at this time.

The Rose Garden.—Hybrid Perpetual Roses should now be pruned, but it is wise to leave the more tender varieties of Teas and Hybrid Teas till later. Give the beds a dressing of well rotted farmyard manure, or a dusting of fertiliser. Point it lightly in between the plants.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Veronica Hulkeana is, in some ways, the most beautiful of all the shrubby Veronicas and is an excellent plant for the cool greenhouse. In the West it does well outdoors planted at the foot of a warm wall, but even then large plants are apt to die suddenly without any apparent reason. Under pot cultivation one seldom sees it in good condition. Although its successful cultivation does not present any serious difficulty, most cultivators, I believe, fail because they keep it too close and warm. It is easily propagated at this time in a case in a cool house, and plants may be grown on into 5in. or 6in. pots the first season, standing them outdoors in cold frames during the summer, leaving the lights off on every possible occasion. If potted on the second season such plants should make fine specimens some 3ft. or 4ft. high. Cool treatment and plenty of air during all stages of its cultivation are essential.

Veronica speciosa and its many fine varieties are very useful for furnishing the conservatory or greenhouse during the autumn. They are easily propagated by means of cuttings, and only require cold frames for their successful cultivation.

Veronica diosmæfolia is a very dainty, compact species, about 1ft. in height, and produces its pale lilac-coloured flowers in great profusion during March and April; it is easily propagated by means of cuttings, and, like the others, enjoys perfectly cool treatment at all stages of its cultivation.

Impatiens Balsamina.—The common Balsam is a popular and useful annual for conservatory decoration during the summer and autumn months, and by making successional sowings it is easy to maintain a constant display. Towards the end a sowing may be made at this time in a temperature of 55°; sow thinly, and when germinated keep the plants well up to the roof glass, as they draw out very quickly. To prevent this they should, as soon as possible, be pricked off singly into small pots, placing them well into the soil, and at each successive potting they should be let well down in the pot, as they throw out roots from the stem and it helps to keep them dwarf. They require at all times a light, rich compost—some old Mushroom bed manure or well decayed stable manure should be added to the potting compost. Later on in the season they are best grown in a cool house—or even in cold frames.

There are several other species of *Impatiens* that are most useful for furnishing the greenhouse and conservatory during the summer, or, in fact, a warm greenhouse all the year round. *Impatiens Sultanii* is an old favourite, and is easily raised either from seeds or cuttings, and the same applies to the newer *I. Holstii*, a batch of seedlings giving quite a range of colours. The best seedlings can then be selected and propagated by means of cuttings. The beautiful *Impatiens Ohyeri* is the giant of the race, and if grown on in tubs, makes fine specimens some ft. in height and as much in diameter. If planted out in a bed in the conservatory it will grow 6ft to 7ft. high and remain in flower more or less all the year round, its large rosy-mauve coloured flowers bearing a striking resemblance to a *Milvina*. It is easily propagated by means of cuttings, and plants in 7in. pots are useful for furnishing the stages in the conservatory.

Campanula isophylla and varieties *alba* and *Mayi* make fine basket plants, for which purpose they have long been favourites. About this time plenty of good cuttings should be available, which will root readily in a case in a cool house, and should make good plants for autumn flowering. The variety *Mayi* is stronger growing and soon makes fine plants if three are grown in a 48 sized pot. It differs from the type in having greyish tomentose foliage.

Capsicum annum and its numerous varieties are very useful for furnishing the conservatory during autumn and early winter, their bright colouring and varied shapes always attracting attention, while their fruits are also useful in the kitchen. Seed should be sown in an intermediate temperature at this time, and when the seedlings are large enough to handle they should be pricked off singly into 3in. pots, potting them on as they require it, 7in. pots being large enough for the final shift. They require a rich compost and should be kept well and regularly syringed as they are very subject to attacks of red spider and also *Begonia* mite. The latter may be prevented by the use of Caniphell's Sulphur Vaporiser. During the summer the plants may be grown in cold frames.

Solanum Melongena, commonly known as the Egg Plant, is grown for decorative purposes, and seed should now be sown. This plant succeeds under the same treatment as recommended for *Capsicums*. *Solanum pyracanthum* and *S. integrifolium* are both worth growing for their bright-coloured fruits, which are useful for the autumn furnishing of the conservatory; they are easily raised from seed at this time, and can be grown in a cool house or even outdoors during the summer.

Royal Botanic Gardens, Kew.

J. COURTIS

OBITUARY

HARRY A. BARNARD.

THE many old friends, spread all over the world, of Mr. Harry A. Barnard will regret to hear that he passed away on March 14. He has entered his well earned rest after serving over sixty years with his firm, Messrs. Stuart Low of Bush Hill Park, and formerly of Clapton. A real plantsman, he had forgotten more than many horticulturists know to-day, but it was by his kindly help to and sympathy for others that he will best be remembered. Commencing his career with the Hugh Low who started the firm of that name, he has seen many of his old comrades predecease him, but three of them at the graveside at Abney Park Cemetery, Messrs. W. Isbell, E. Groves and Fred Jenkins, have served the firm in the aggregate for some 130 years. This is the second old comrade to pass away since Christmas. The late Mr. "Ted" Heath had been with the same firm for nearly half a century. F. J. C.

Winter Flowering Carnations at Wisley: Interim Report.—The following awards were made to Carnations at Wisley by a Joint Committee of the Royal Horticultural Society and the British Carnation Society. The judging was solely on the productiveness of the plants during the winter and upon their habit, and the colour and form of the flower. Award of

Merit—*Wivelsfield White* and *Mame Sunshine*, both sent by Messrs. Allwood and Messrs. Engelmann; *White Pearl*, sent by Messrs. Stuart Low; *The Herald*, *General Joffre*, *Aviator* and *Jazz*, all from Messrs. Engelmann; *Toreador*, sent by Messrs. Allwood. Highly Commended.—*Whiteall*, sent by Messrs. Stokes; *Mrs. Walter Hemus*, *Enchantress Supreme*, *Triumph* and *Wivelsfield Beauty*, all from Messrs. Engelmann and Messrs. Allwood; *Cupid*, *Lady Northcliffe*, *Mary Allwood*, *Peachontas*, *Mrs. Hamilton Fellowes* and *Iowa*, all from Messrs. Engelmann; *Lady Inverforth*, sent by Messrs. Stuart Low; *West Hall Scarlet*, sent by Mr. G. Carpenter; *Countess of Wilton*, sent by Messrs. Engelmann and Messrs. Stuart Low. Commended.—*White Wonder* and *Benora*, sent by Messrs. Allwood and Messrs. Engelmann; *Boadicea Nebraska*, *Fancy Carola* and *Marion Willson*, all from Messrs. Engelmann.

The Rose Annual, 1922.—This excellent publication, which is issued free to members of the National Rose Society (minimum yearly subscription, *res. 6d.*), teems, as usual, with interesting articles. A portrait and pen picture is given of that famous Rose raiser, Mr. Samuel McGredy, with interesting details as to how the hybridising and raising of new varieties is carried on. Other articles include "Roses in Pots," by the President of the Society, Mr. Edward J. Holland; "Notes on the History of the Moss Rose," by Major C. C. Hurst; "Bedding Roses," by Mr. H. R. Darlington, with reasoned opinions as to the best dozen for the purpose by eight experts in various parts of Britain; "Chemical Manuring," by Major A. D. G. Shelley; "Recollections," by the Rev. Jos. H. Pemberton; "Notes on the Spring Show," by Mr. H. Oppenheimer; "Exhibition Roses for Garden Decoration," by Mrs. H. R. Darlington; "Impressions of the Summer Show," by Mr. H. H. Thomas; "The Provincial Show," by Mr. A. C. Bartlett; "The Imperfections of Modern Roses," by Mr. John Parkin; "Climbing Hybrid Tea, Tea and Noisette Roses," by Mr. Walter Eastlea; "Budding Roses," by the Editor (Mr. Courtney Page); "Climbing and Rambling Roses in Gloucestershire," by Mr. B. W. Price; "Notes on Mildew and Black Spot," by Dr. Sauer; "The Newer Foreign Roses," by Mr. George M. Taylor; "New Roses at Bagatelle Trials," by Mme. Charles Siret; and "New Roses of 1921" and "The Rose Analysis, 1921," both by the Editor. Besides all these, our valued contributor, the Rev. Joseph Jacob, at present convalescing, we trust, from a serious illness, contributes in his inimitable way his impressions of the Autumn Show. In addition to all this very interesting matter and the portrait of Mr. McGredy already referred to, there are numerous half-tone illustrations, including a portrait of Mr. John Green (a new Vice-President) and blossoms of that wonderful new yellow Rose *Florence M. Izzard*, besides pictures in colour of *Mabel Morse* and *W. E. Wallace*, both Roses honoured by the Society in 1921. When one considers the many advantages offered to members by the N.R.S. and the quality of its publications it is small wonder that the membership roll is a long one.

Tomato Cultivation Under Glass and Outdoors.*—The author of this booklet has done good service to all cultivators of Tomatoes by writing a really charming essay on a very popular subject. Last year was an exceptionally good one for the growth and ripening of the Tomato, but it will also be long remembered as a year in which the destruction of the plants, almost throughout the country, was threatened by the white or "ghost fly." Many cultivators may

have decided on that account not to grow any plants this year but if they read this small book they will at once decide to grow more plants than in past years. No one should be without the book, not even large cultivators for market, as the instructions on the destruction of the "ghost fly" are so valuable. When one begins to read the book one feels one must go on to the end. Amateurs especially will find the instructions so helpful to them. They cannot fail, as the instructions from the seed-sowing to the seed-saving chapters, are concise, clear and to the point. There are several drawings showing how the planting and stringing of the plants should be done, and although the one showing the section of the house might be clearer—page 11—it shows the cultivator what he must do and how to do it economically. The raising of the seedlings, potting, training, feeding, fertilising of blossoms, fumigating, gathering and packing for market, private use and exhibition, insect pests and diseases, and the general management of the plants in various kinds of houses, small and large, are matters admirably dealt with. It is a pleasure to recommend a book containing so much valuable information in such small compass.—G. GARNER.

A Lovely Stonecrop.—A good number of the *Sedums*, or Stonecrops, are of considerable beauty, but, somehow they do not appear to be so largely cultivated as they deserve. They are generally specially suitable for dry, sunny positions, and mostly thrive in stony or gravelly soil unsuited to the majority of alpine plants. Of the large number in cultivation a few stand pre-eminent in their beauty, and should not be omitted from the choicest collection. *Sedum brevifolium* is one of these, and no matter what form of this Stonecrop is secured, there is little risk of its being unappreciated when properly cared for in the rock garden or the moraine. It has been well called "one of the brightest jewels of the race." It is among the tiniest of Stonecrops and provides a dense carpet, hardly rising above the soil, of charming little leaves varying in colour, according to the form, from green to purple, with many intermediate tints. The flowers also differ in colour, ranging from pink to white, often flushed with delicate pink or blush, and are of a good size for such a dwarf plant. One of the best forms in cultivation is that called *S. brevifolium* var. *Pottsi*. This was brought from abroad by the late Mr. Potts of Edinburgh, a keen flower-lover whose memory is also kept alive in *Montbretia Pottsi*. This variety is very beautiful, but it is impossible to describe in words the colouring of the foliage, which seems to consist of shades of green, purple and dull white with various other colours and with a pretty appearance caused by the larina-like shading of the foliage. Any form, however, is worth securing. Unfortunately, *S. brevifolium* is liable to decay in wet winters in certain districts with mild climate and a heavy rainfall. In such districts it is always prudent to protect the plants from the weather for a few of the winter months, say, from November until March, either by a sheet of glass or some other shelter, raised a little above the plants so as not to interfere too much with the light if the protection (such as a slate or board) be such as would prevent it from reaching the plants.

A very freely drained place should always be selected, with a gritty, open soil and a sunny situation. The variety *Pottsi* may generally be seen in the Royal Botanic Gardens, Edinburgh, where it seems to stand the winter better than on the more humid west coast. There is no difficulty in propagating *S. brevifolium* by division or by cuttings. It is found, among other places, on the mountains of Spain and Corsica.

PERPETUAL CARNATIONS ILLUSTRATED
—A thoroughly practical and well illustrated book on these beautiful and popular flowers, written by LAWRENCE J. COOK is now ready. Price 2/6 net, postage 4d. extra. It is published at the Offices of "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

A VISIT to the R.H.S. meetings at this season of the year, displays a wonderful variety of flowers—a variety which is not, in fact, just at present reflected in our gardens. The predominant note in gardens for a week or so to come will be provided by the beautiful family of Narcissi with their considerable range of colouring and immense diversity of size and form from the saucer-cupped—if the bull may be forgiven—Poeticus forms to the great trumpet Daffodils. Tulips—especially the early-flowering sorts—have a staid primness which makes them most successful when used in formal beds and borders. The freedom and grace of flower of the Narcissi, on the other hand, allied with an equally gracious and free arrangement of leaf and flower in a naturally grown clump, are seen to best advantage when they are massed as naturally as possible. Happy is he who has open woodland, orchard or rough pasture to plant with these beautiful flowers, but almost every garden would provide a place where they would look delightfully natural. We hope next week to show happy groupings of this favourite flower in various situations, but it is by visiting at flowering time grounds where they are happily placed that one gains much essential knowledge as to their arrangement for effect.

Another Advance.—The beautiful new white trumpet Daffodil White Dame gained an award of merit "as a show flower" at the Royal Horticultural Society's Forced Bulb Show on March 14. It was raised by Mr. Guy L. Wilson of Broughshane, Co. Antrim, who showed five lovely blooms. It is chiefly remarkable for the fine pose of its perianth, which stands flat and at right angles to the trumpet, its exceptional whiteness and considerable size. It is said to have a vigorous constitution and to make broad foliage and large bulbs. Though it obviously would not withstand rough weather outdoors, this is undoubtedly a great advance in white Daffodils.

The Water Garden.—Water does not, in springtime, respond so quickly to the increasing power of the sun's rays as does the kindly earth, indeed it is a well known fact that water-logged soils remain cold where well drained, reasonably dry ones rapidly warm and so encourage the growth of plants. This property of water is, in reality, useful to the gardener inasmuch as it enables him to undertake

planting of aquatics when growth has made much dry-land planting inadvisable. True aquatics may be planted at any season before growth is completed, but it is as well to get them in reasonably early. This being so, the time has come to carry out the formation of new water gardens or to make any necessary alterations to existing work. The article in this issue touches only on details of construction. The question of design will shortly come under consideration.

The Working of the Land.—It is but too usual, at this season of the year, to get inclement weather. Of the necessity for protecting early crops it is probably unnecessary to speak, but it may be well once more to emphasise the danger of working on the land when the surface is wet, more especially after a fall of snow, hail, grapple or sleet. These wholly or partially congealed forms of rain, though

harmful to early crops, are really beneficial to the majority of sown seeds, inasmuch as the extremely penetrating quality of the moisture they provide greatly assists the germination of hardy seeds. Asked "how the land was," when the soil was wet after such a storm, a very old-fashioned gardener said, "quite all right if you keep off it," and that exactly sums up the situation.

Ply the Hoe.—The showers for which April is famous, whether very cold or warm and genial, will tend to consolidate the surface of the soil, though the amount of "setting" as gardeners generally call it depends very largely upon the character of the soil itself. Some soils and those of very varying appearance and texture are notorious for their tendency so to "set," while others give no special trouble in this respect. Aeration of the soil is a

stark necessity in gardening and such a tendency for the surface to consolidate must be constantly combated with Dutch hoe or pronged cultivator, whichever suits better the particular crop or has been found to give, on the particular soil, the most lasting results. Such cultivation is doubly useful. It not only encourages the plants; it discourages the weeds.

The Invaluable Annual.—It is remarkable how much the annual especially the hardy annual, is still depreciated, almost tolerated, by many enthusiastic gardeners. This is partly due, no doubt, to the fact that whatever can be raised from seed in a few months must necessarily be common. There are many whose chief pleasure lies in growing plants they seldom see in other gardens. The commonest reason for the neglect of annuals is that they have been tried and found wanting. The reason for this undoubtedly is that the average gardener does not sufficiently study the requirements of the different genera. Just because their season of growth is short it is imperative, if success is to be obtained, that they be given soil and aspect which suit their particular requirements and that they receive care in the matter of thinning and such like proportionate to their rapidity of growth. It is useless to expect Mignonette to thrive on sour soil or Eschscholtzias in semi-shade. In one respect, however, almost all kinds are alike—they appreciate a deeply and thoroughly cultivated soil. Annuals are, taking them as a whole, lighter in growth than perennials and this characteristic renders them admirable for cut flower.

THE HANDSOME PAPER-WHITE NARCISSUS WHITE DAME.

PRIMULAS FOR ROCKERY AND BORDER

There are few families of garden plants more indispensable than the Primulas. We are describing this week some of the most noteworthy for the rock garden and for beds and borders.

WHAT is the rock garden going to show us during the next few weeks? To-day, while the woods are yellow, there is a wonderful patch of blue in a shaded dell, a patch that owes its colour to the blue Primrose. This is said to be less vigorous than the wild type and to seed less freely. The latter is true: as to the former, it all depends upon cultivation. It can be as free and wonderful as any, little tufts of dozens upon dozens of varying blues that are worth a long journey to see. It is easy to raise from seed and easily divisible after flowering. Put down in half shade a patch of really stiff loam that inclines to clay, and there, if suitably enriched, you can be sure of the almost extinct double forms, in white, yellow and red, doing well. They are pretty little flowers, carried on by division as they form no seeds, that it is a pity to lose.

Every week—until July is passed—sees some new beauty expanded, reaching the climax in April and May and I think the best way will be to glance, according to their months, at just a few of them.

During April, one of the most forceful colours of all is provided by the wonderful moisture-loving *P. rosea*. This dies out again and again, unless planted where it is always abundantly supplied with moisture but, when happy, makes a very close and compact little rosette of leathery leaves, surmounted by trusses of carmine-pink Polyanthus-like flowers, sometimes as many as half a dozen being produced by a single plant.

Those charming mauve flowers, produced singly or in pairs, are *P. Allionii*, and please note how happily it thrives in that rock-crevice, where it will continue to flower almost until midsummer. Not far away, sheltered somewhat by an overhanging crag and surrounded by chippings so that the soil cannot become splashed upon its wonderful gold farina, is *P. bullata*, a Chinese species, with lance-shaped leaves and golden yellow flowers. It loves shelter and lime, hence the limestone chippings that surround it. *P. elatior*, the Bardfield Oxlip of the holds, both in its more familiar yellow and several colours, thrives anywhere and is a good perennial. *P. Forbesii*, often grown in pots, is never quite dependable in the open ground; sharp winters invariably kill it, but it is worth keeping in pots in a cold frame and planting out in spring to flower—a treatment often afforded to many a less valuable plant. Given a rich sandy loam and plenty of leaf mould, the fine downy foliage will develop to perfection and the flower stems will attain a height of 6 ins. to 8 ins. The flowers are magnificent, 1½ in. to 2 in. across, a lovely rosy pink with deep orange centre. *P. hirsuta*, a very desirable alpine Primula with woody stems and rosettes of handsome leaves covered with downy glandular hairs, should not be omitted. The flowers arise in umbels, varying from carmine to purple. This plant flourishes best in very well drained sandy loam and peat that runs deeply between crevices and fissures in the rocks. A variety or hybrid of this is *P. pubescens alba* (*P. nivalis* of gardens), one of the most charming of April-flowering species. *P. involucreata* also needs the margin of the bog to succeed, as do so many of the Himalayan species, and then rises to a height of 6 ins. The plant itself is in the form of a rosette of bright shining leaves, with numerous stems of fragrant bluish white flowers in umbels. *P. scotica*

is one of our own native species that is considered—by some—to be only a variety of *P. farinosa*, the Bird's Eye Primrose. The plants are very irregular in their flowering, sometimes deferring this until as late as June. They succeed best treated as biennials. With the month of May, however, comes the zenith hour of Primula time, when fresh species crowd upon the stage one after another, until—wherever one looks—Primulas seem to hold all the important positions, though Saxifragas run them very close.

Prominent at this season is *P. cortusoides*, of gardens, with lovely clusters of deep rosy pink flowers. It is readily raised from seed and loves a sheltered home where a large stone or shrub protects from cutting winds, though it must not be unduly shaded. A relative of the Bird's Eye Primrose, though larger and finer in every way, is *P. longiflora*, with lovely deep lilac flowers, the tube of which often runs to an inch in length. It is a species that needs a little care, planting on a slightly elevated position in moist fibrous soil, covered during summer with a layer of small stone chippings to check evaporation. *P. saxatilis* is another gem, one of those vividly coloured light-growing little plants that count. The leaves are small and the flower stems—which are very numerous—rise to a height of about 6 ins., with clusters of vivid rose pink blooms at the top.

One hardly knows whether to place the Auricula under April or May for the flowering season, for different plants always flower at different seasons, so that they overlap from the latter half of April into May. What richness and depth of satisfaction there is in the glorious velvety flowers! Vivid golden yellow, soft primrose, heliotrope, crimson, fawn, brown, purple, all with conspicuous eye and with the colour paling off slightly towards the edge of the petals. Round the edges of large

beds, in great clumps on the mixed borders and here and there in the rock garden, the display they make is superb. Surely, the acme of Primula refinement has, in them, been attained. Slightly less refined, perhaps, but a grand old flower all

PRIMULA MARGINATA IS BEAUTIFUL IN FLOWER AND INTERESTING IN FOLIAGE.

ONE OF THE FINEST OF THE AURICULA-LEAVED PRIMULAS—
PRIMULA HIRSUTA CILJATA.

the same, the Polyanthus wins easily when it comes to mere garden display. The lighter colours are especially showy. One loves to have these in great masses, not by dozens, but hundreds—or thousands. Packed closely with Tulips between they give a display on two levels that no summer scene can excel for colour intensity. Tulips of 15 ins. and upwards in stature should be chosen for thus interplanting, so that they are well clear of the heads of the Polyanthus. Does the Polyanthus provide any material for the rock garden? Certainly it does. Are there not the superb gold laced forms where, allied to a rich petal so deeply coloured as to appear almost black, you have a sharply marked clear gold margin, picking out the flower in very striking manner? Then, too, the blue, a rarely seen flower although perfectly easy to raise in quantity from seed. The plants are perfectly hardy and nearly as vigorous as the commoner type. Seed should be saved only from plants bearing the cleanest and bluest flowers. It is surprising how it is possible to improve the strain.

P. marginata is invariably charming as it nestles down in its little pocket and can always be distinguished by the silvery meal margin that decorates each leaf as though touched by some unusual hoar frost. The flowers are a soft violet rose and sweetly fragrant. The best way is to replant annually, sinking right down to the lowest leaves, for the plant is a regular stilt-walker and raises itself high above the soil in a very short space of time. Where replanting is neglected, the plant is but short lived, for the roots, that push from the stems, perish, and no amount of top dressing suffices to keep the plants "earthed up." *P. Parryi* must be placed where the roots are always really wet; it is almost impossible to provide too much moisture, provided this does not stagnate. The flowers are nearly an inch across, borne on stems fit, high, in heads of about a dozen and of deep tyrian purple. *P. Sieboldi* luxuriates in a light, moist, open soil, where the roots can creep just below the surface, for they have the unusual property of forming eyes here and there as they extend, thus giving rise to new plants. This enables the many beautiful named types to be re-produced perfectly true. These include some of the grandest of all

VARYING A LITTLE IN ITS SLATY HUE, THERE IS MUCH QUIET CHARM IN
PRIMULA INVOLUCRATA.

rock garden Primulas, with a wide colour range and great freedom of flowering, some of the most beautiful having fringed edges to the petals. This beautiful species is not, however, hardy everywhere.

P. villosa claims to be one of the oldest species grown in gardens and is readily recognised by the leaves, which are slightly sticky on both sides. It is an easy form to grow, simple to divide and readily raised from seed. *P. Aretotis* is a very interesting plant to possess as it is a hybrid between *viscosa* and *P. Auricula*, with spoon-shaped leaves and white or lilac flowers. *P. calycina* has leaves

that are glossy above and glaucous on the underside with small trusses of purple flowers.

Growing in large loose-leaved rosettes *P. carniolica* is a very desirable species, especially its variety *multiceps*, which bears larger and deeper blue flowers than the type. These are in heads, from three to ten in number, on stalks between 2 ins. and 4 ins. high, with light centres. For rich moist borders or open parts of the rock garden, *P. luteola* is a very showy form by reason of the depth of its round heads of pale yellow flowers, a striking contrast to the deeper centre. Lest you pass it by, stoop down and look closely at the Fairy Primrose (*P. minima*). Minute indeed are its proportions for it is only between 1 in. and 2 ins. high, with foliage scarce half an inch in length. The flowers are generally solitary, occasionally to be found in pairs and generally rose pink in colour, more rarely quite white. The plants flourish in chinks between rocks, where they can tuck their roots deeply into moist light loamy earth. The plant is of special value to those interested in hybridisation, for *minima* has a great disposition to fertilise with other varieties, growing near it. Therefore the deliberate transfer of the pollen gives a good chance of something new.

P. uniflora is a worthy species with which to conclude our May-flowering forms and a most unusual and interesting plant. The flowers are pale lilac in colour, usually one, but sometimes a couple on the scape and exceed in size that of the whole rosette of small leaves. It must be grown in patches so as to secure the best effect, the plants appreciating a moist sandy soil and a sheltered position.

I have not attempted to mention all the species—even all the good species, let alone hybrids and varieties, which make the rockery beautiful at the season under notice. I have not spoken, for instance, of those allies of *P. Sieboldi*, *P. Veitchii* and the even more beautiful *lichiangensis* with its curious rich brown calyces, nor of the many beautiful hybrid miniature *Auriculas*, such as should properly be classed as *P. pubescens* var. *Mis* J. H. Wilson, or what not, but which, too often, are set down as forms of *viscosa* or *hirsuta*. H. W. C.-W.

PERHAPS THE BRIGHTEST ROSE-COLOURED FLOWER THAT GROWS—*PRIMULA ROSEA*.

BORDER CARNATIONS FOR THE BORDER

Their treatment at this season to produce the best results.

THOSE who are fortunate in their gardens are able to indulge in autumn planting in full confidence that when March arrives and their Carnations commence the season's activities the stock will be fairly complete, and, what is a great asset, well established. The less fortunate must winter their Carnations in frames and plant them out at about the present time.

It does not seem so long ago when the rival virtues of autumn and spring planting were the subject of much controversy, each school "upholding their various opinions," though without undue heat. As ever, Nature has the last word, but it is generally agreed that, where soil and climate permit, autumn planting is to be preferred with the hardy sorts, and the reasons are fairly obvious. The recent heavy rains which have been so welcome in replenishing our depleted store of water have caked the surface soil in many gardens and where the Carnations are already established the first work connected with them is to ply the hoe to loosen and aerate the soil. A light application of some chemical stimulant at intervals from now onwards, till the flowering season arrives, will be very beneficial. The chief Carnation specialists offer mixtures which they claim to have found valuable and the excellence of their flowers fully justifies the assertion. For those who prefer to mix their own fertilisers the following formulae are suggested. Sulphate of ammonia 2 ozs. and super phosphate 4 ozs. per square yard. This is a good stimulant if the Carnation bed was well made previous to planting out the runners. Where doubts exist it would be well to add 1 oz. of nitrate of potash to the above. But whatever mixture is used care must be taken not to spread any on the leaves as they are liable to be scorched.

When making preparations for planting out the young plants that have been wintered in frames, the two chief essentials for success with Carnations should be kept well in mind. Carnations abhor shade, insisting on direct light. Good cultivation must be practised. These points observed it will be found that, given healthy stock to commence with, Carnation growing is a comparatively easy matter. Although the Carnation will grow and flower well in the average flower garden soil, when properly prepared, the ideal soil is a medium loam

(one that is neither light or sandy nor inclined to be clayey), that contains enough grit to render it porous. In cold gardens where rain water is liable to lie on the surface it is wise to make raised beds over ample drainage, but otherwise they are best on the level. Lime in some form is a necessity for good Carnations and when old mortar rubble can be procured this is one of the best methods of providing it. Should the soil be poor in plant food it will be necessary to add manure, and any of the customary forms will be suitable, always provided

A BORDER OF CARNATIONS APPROACHING BLOSSOM, SHOWING METHOD OF SUPPORTING WITH SHORT TWIGGY STICKS.

that it is not too fresh and raw. Spent Mushroom beds or matured farmyard manure that can be broken up, are the ideal forms of organic manure. Failing these use must be made of such as bone meal, basic slag and superphosphate of lime. Bone meal is not the most economical source of phosphates, but it is safe and sure and for a special purpose the little extra expense is often not a great matter. Formerly basic slag was used almost solely as a winter dressing, because in the form then only available it was very slow acting, but with improved machinery and methods it can now be obtained ground much more finely, and so

provides an efficient and cheap phosphatic manure for spring as well as autumn use. For Carnations it can well be used at the rate of quite 4ozs. to the square yard and should be well mixed with the soil, keeping it away from the surface and down in the root run.

Where a good show of bloom is desired and fresh plants are set out annually, a distance of 12ins. to 15ins. may be allowed from plant to plant, but if the plants are to remain for two seasons they will require an additional 3ins. each. A common error when planting is that of setting the plants too deeply in the soil. This should be avoided and the crown of the plant kept up as much as possible, always provided that the roots are sufficiently covered with soil. An objection to shallow planting is that there is a danger of wind disturbance, but this may easily be guarded against by either tying each plant to a short stake or by placing three closely around the plant.

The selection of varieties is always a matter open to much criticism and divergence of opinion, but I will hazard the following as being a satisfactory dozen. Bookham White, Border Yellow, Dora Blicke (orange-apricot with a sheen of gold), Elizabeth Shiffner (a handsome orange-buff), Fujiyama (an intense scarlet), Grey Douglas (a fascinating deep heliotrope with a sheen of French grey), Gordon Douglas (bright crimson) Duchess of Wellington (lavender), Innocent (pale salmon pink, almost a blush pink), Mrs. A. Brotherton (heavily splashed with crimson-purple on white ground, clove scented), Rosy Morn (fine rose pink), and last, but not least, Bookham Clove, a splendid crimson flower with a delicious perfume which "rivals the old Clove." This latter may be a matter of opinion, but it certainly is the best clove-scented Carnation we possess to-day, though it cannot equal the old original Clove Carnation, which has so long been lost to our gardens, of which it was said that the perfume was so strong and powerful that one plant would scent a whole garden.

A. CECIL BARTLETT.

A BEAUTIFUL CLEMATIS

AMONG the more vigorous climbing section, *C. Jouiniana* is one of, if not the best hybrid of the Clematises raised in gardens. Its parents are *C. Davidiana*, one of the heracleæfolia or sub-shrubby section, and our native species, *C. Vitalba*, the Traveller's Joy of our hedgerows. Free and strong in growth, it is an ideal climber for arches and pergolas. One of the best uses to which I have seen it put is clothing a very large stool of a Beech tree. When the tree was grubbed up, instead of disposing of the base, it was turned over, half-a-dozen plants of this Clematis were planted round it, and to-day every part of the stool is hidden with leaves and flowers. The leaves are dark green in colour, with almost a leathery texture. The flowers are white, tinged with blue, especially on the outside, about an inch across, and are freely produced in axillary panicles. In one catalogue the colour is described as mauvy white. One of the most important features of this hybrid is that it is autumn-flowering. Commencing early in September, plenty of blooms are usually to be found on the plants till frosts intervene. Unfortunately, some confusion exists with regard to the name. In many gardens this plant is grown as *C. grata*, but the true plant bearing this name is a Himalayan species. The latter, however, is very rare, and readers who obtain a plant under either of the names mentioned will be fairly sure to get *C. Jouiniana*.

A. O.

ECONOMICAL WATER-GARDENING

Much water and, consequently, money is wasted through bad planning and faulty construction. Follow some hints on sound construction and wise design.

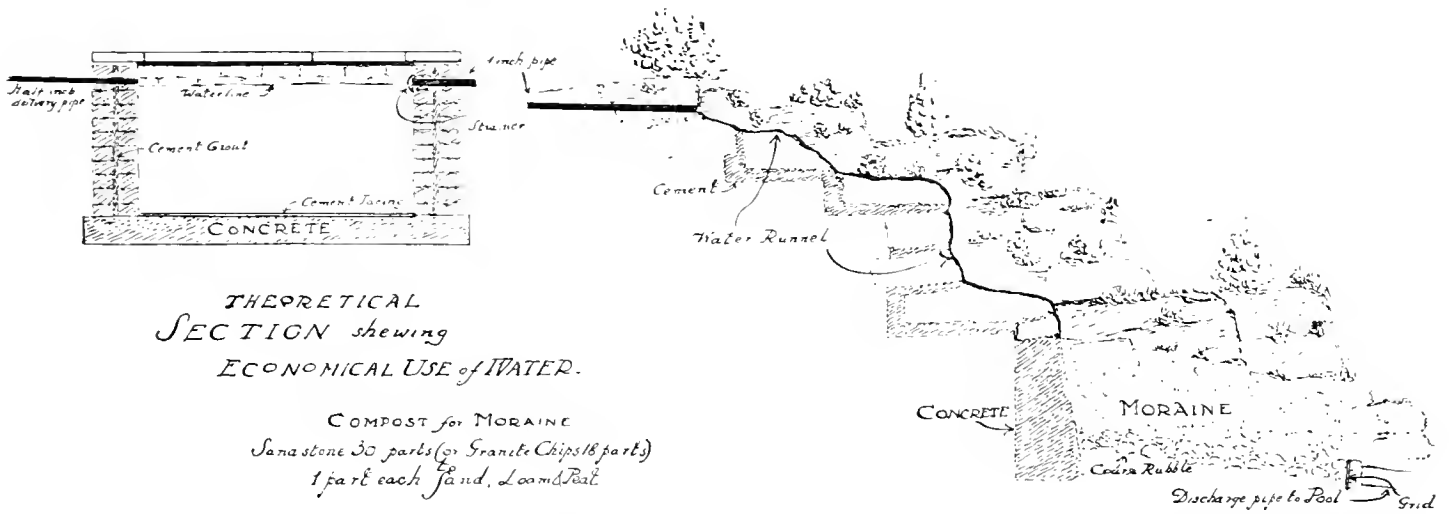

HERE are, throughout England, many Lily ponds and water gardens of which the only source of supply is surface drainage from land near by, and, it may be, from the roofs of buildings. Such an arrangement is never over-satisfactory, since in wet weather much water is emptied into the tanks or ponds in little time, while in periods of drought the level of the water falls very considerably or it may even fail altogether. It is astonishing what resistance Nymphæas offer to such conditions of drought, but the waterside planting inevitably dies out and the drying ponds, if anywhere near

Water power is really, in our climate, much more amenable than wind power, and in many country places a good and continuous supply is provided at a purely nominal running cost by the use of hydraulic rams. For domestic supply the power is usually provided by a convenient brook and the water delivered by a well, but where the garden only has to be provided for, the brook water itself is usually preferable to the cold spring water, so desirable for drinking and cooking purposes.

So much for the original supply, but it is rather of the economical use of water in the garden—

outlet very much lower down will then supply water to the standpipes with hose connexions which are so great a stand-by in the garden. When, some hot summer's evening, an orgy of watering is in progress, the trickle to the water garden will probably go dry for a few hours, but that will matter little if at all.

Now for the arrangement of the waterways after the precious fluid has left the securely jointed iron pipes which re-deliver it to the light of day. In order that it may not be lost as it trickles through the rock garden the channels should be cemented *below the level*. The stones over which

The illustration depicts the overflow from a Lily tank in the more formal part of the garden supplying the trickle of water which so enhances the appearance of the rockery, next watering the moraine and finally maintaining the informal pond in the rock garden.

the residence, become an insufferable nuisance, at once an offence to the sense of smell and a source of danger to health.

It is apparent, therefore, that unless a reliable natural supply is to hand some arrangement should be in existence to maintain the water supply. In many suburban gardens this is, no doubt, most readily effected by "laying on" the water supplied by a company or public body, but it must always be borne in mind that such supplies are but too liable arbitrarily to be cut off in time of unusual drought—just when, in fact, they are most needed.

What then remains? There are very few localities in which a well may not be sunk to reach water at a depth of roof, or less. In some districts a very few feet suffices to provide an excellent supply. Such a well, if the water be not too hard, will, with the assistance of an oil-driven pump, provide an ample supply. A few years ago there was a big demand for wind-driven water pumps which, although admittedly ugly, were supposed to pump water with little further cost than the original outlay. Experience has, however, proved that while some of these windmills are better designed and more effective than others, the best of them, owing to the cost of repairs, renewals and upkeep, are little, if any, cheaper in working than the power pump. They are not, in consequence, being installed to-day to anything like the extent that they were a decade or so ago.

since it is often expensive to procure—that the writer wishes to treat.

The same water may usually be made use of to provide the very desirable trickle in the rock garden, to water the "moraine" and to supply the water garden. For this reason it is very desirable to decide upon the lay-out of these three features at the same time, even though, for one reason or another, it is not intended to construct them all simultaneously.

It is wonderful what effects and benefits may be obtained with proper precautions from the supply produced by a half-inch pipe! The water, by the engine or ram as the case may be, should be delivered to a large tank which, if circumstances permit, may be built in adjacent high ground, but as they very seldom do permit, usually occupies the top floor of a water-tower. Such towers are certainly most "eyeable" when built of orthodox materials, such as brick or stone, and properly roofed. Their lower storeys then become available for some purpose for which space must be provided. There are many cases, however, in which the house is already in existence, and a water supply is urgently required but no additional outbuildings. The large cylindrical steel tanks on steel ganties then come in for consideration as being at once practical and relatively cheap.

However the tank be accommodated, the outlet for the rock garden fall, moraine and water garden should be near high-water level and another

it runs should be bedded in an inch or two thickness of good concrete and the joints between the stones made good with strong cement of the strength of "one and one" (one part clean sharp sand, preferably washed, and one part fresh, dry Portland cement). Bits of stone bedded in these joints before the cement has set will maintain the appearance of the work. Whatever pains be taken there will be a loss of water in its progress, however short, through the rock garden. This loss will arise partly by the splash, which will enable Ferns and damp-loving plants to flourish, and, especially in summer, very largely by evaporation. Where the supply is limited, therefore, one should not take the water by too devious a route.

We will suppose that, in natural sequence, the water next supplies the "moraine." "Moraines," when first attempted in Britain, usually had a sloping concreted bottom down which the water trickled on its way to the outlet. There was, of course, a loss by the capillary action for which the water was provided, but there was no measurable loss by soaking away. Experience has proved the concreted moraine unsatisfactory, so, to avoid total loss, the bed of the moraine should be made quite steep and no attempt should be made at the underground pool, which was the first idea of moraine makers. If the supply is taken direct to the moraine the pipe may be taken across the head of the latter, and so perforated as to water every part, but where, as

suggested, the moraine is supplied from the rock garden trickle, the moraine should not be over-wide or parts may quite fail to receive their share of water.

We have now left to consider the water garden proper. Where this consists of a little more than a Lily tank the matter is a comparatively simple one from a constructional point of view—its design is another matter. Such a tank should have a base of best concrete at least 6 ins. thick, this being itself faced with a highly smoothed surface of "two and one," or if the sand is not quite first-rate, of "one and one" cement. "Rendered, floated and set" is the trade designation for the finish which should be given. The sides may be of concrete similarly faced with cement, but they will look better if formed of stone, or even brick, filled in solid behind to a depth of 6 ins. or so with grouted concrete. This operation needs great care or the tank may prove leaky, and its repair will considerably inflate the total cost.

An informal pond with surrounding bogland presents other problems. This may be concreted in the way already described, but the concrete must pass right under the bogland which surrounds the water and must either be "dished" so that

it rises above water level at the edges or a proper watertight wall, as already described, must run behind it—below the ground, of course. If an extensive waterside bog garden is contemplated a good water supply must be arranged for as the evaporation from the bogland is much more rapid than from the surface of the water itself.

The waterside bog is ideal for the huge Candelabra Primulas—pulverulenta, japonica, Bulleyana, helodexa, sikkimensis, etc.—for Spiræas, Saxifraga peltata and other large-growing water-loving plants, but where little colonies of the water-loving Gentians, Pinguiculas Sarracenias, Trilliums, Cypripedium spectabile, Saxifraga granulata and even Primula rosea are desired, it will be well to provide a miniature bog supplied with running, rather than stagnant water between the moraine and pool level. This is easily contrived, and since water-loving plants are almost invariably fascinating, very desirable.

Of the planting of these various desirable features—the moraine, the rockery trickle, the running bog, the pool and the waterside—all of interest during the coming month or so, we shall hope to write during the next few weeks.

THE USE OF NETTING IN THE FRUIT GARDEN

The cultivator of hardy fruits, with many years' experience, knows well how essential it is to success that sufficient netting be available and that it be kept dry and in the best condition possible. The time has come again when every effort must be made to preserve the fruit blossom from damage by frost.

THE judicious placing of nets over fruit trees on walls not only preserves the blossom from being spoiled by frost, but hastens the setting of the young fruits and their early growth. Even two folds of fish-netting will make a difference of 4° of heat near the wall surface. Then there is the question of the measurement of netting when the cultivator is buying it. The square-mesh net spreads out more satisfactorily than the diamond-shaped. One hundred yards of the latter will not, when spread out to cover a wall surface, cover more than about 60 square yards. One hundred yards of the square-mesh netting will effectively cover about 80 square yards. Cultivators should bear this in mind when ordering nets from the merchant or manufacturer, as the latter generally measure the net laterally and longitudinally respectively. One thickness of small—½ in. mesh—netting will be sufficient, but the herring-net size will require to be placed on folded double.

As frost strikes downwards, it will only be necessary to cover two-thirds of the wall space from the top downwards. Under the coping make a strong wire secure to the wall; from this wire stretch other wires to stakes driven into the ground 3 ft. from the wall and 5 ft. apart. These wires will support the nets and prevent them blowing against the trees when strong winds prevail. The nets should be fastened to the wire under the coping of the wall, and, when let down, made secure to the stakes by means of strong cord. Nets should never be allowed to lie on the ground when not actually in use, as they soon rot.

To protect the blossom of choice bush and espalier Apples and Pears it is much the best plan to put up a light wooden frame or strong wires to a few wooden or iron posts. The tops

of each post should be covered with a tuft of hay or dried grass, made secure by tying with string, to form knobs, which will prevent the nets being torn. The supports for the nets should be quite 18 ins. above the highest branches of each tree. In the case of espalier trees, cross-laths should be fastened to upright stakes driven in near the centre of the tree and 5 ft. apart. The stakes should be about 1 ft. above the tree, and if wires are fixed to the ends of the T-shaped cross-laths, the nets will have a good frame to bear them up quite free of the branches and blossom. It is an easy matter to make the ends of the nets fast to short stakes driven into the ground at a suitable distance from the tree itself.

Although the leaves of Strawberry plants protect much blossom, the greater part of it is exposed to frosts if they occur, and some artificial protection is necessary. I have found the following simple method very useful and effective. Stakes were driven into the ground in rows 8 ft. apart from stake to stake, the rows being 6 ft. asunder. The stakes were 2 ft. above ground, and wires were fastened to the tops of them and secured to other stakes driven into the ground at the ends of each row. In this way the wires could be stretched tightly. All joinings of the wires and the tops of the posts being covered with hay tied securely, there was little risk of tearing the nets when they were put on or taken off.

I left the posts and wires in position in readiness for the nets again when the fruits were ripening. Without in any way disturbing the nets, one could crawl underneath them and gather the ripe Strawberries at will.

It is advisable to be a few days early in fixing the nets rather than a few too late; before the flowers open have the nets in position.

GEORGE GARNER.

TO ASSIST THE FRUIT CROP

Many an amateur's tree which never fruits could be made productive by a small expenditure of trouble at flowering time.

THERE are, it is well known, many varieties of Apples, Plums and Cherries which are what fruit growers call "self-sterile"; that is to say, that their blossoms must be fertilised by pollen from another variety if fruit is to be produced.

The usual and proper method of overcoming this disability is to interplant such self-sterile varieties with another sort flowering at about the same season, so that insects "working" the trees will have every opportunity to cross-pollinate them. In the case of orchard standards this is the only practicable way of ensuring fertilisation, and if a plantation has been made of, say, Cox's Orange Pippin, either some of the trees must be replaced or the existing trees must be "cut over" and reworked with another variety.

The case of the amateur with a few trees—either bushes, pyramids, espaliers, cordons or fan-trained—is, however, widely different, and it is the amateur who nowadays most often plants self-sterile varieties quite away from any other variety flowering at the same season.

Much may be done by transferring pollen by means of a camel-hair brush or a rabbit's tail to counteract the error in planting. Indeed, leaving the question of self-sterility quite aside, artificial pollination is, especially in "chancy" weather, very desirable in such circumstances and may make all the difference between a good crop and an almost total failure.

Speaking generally, the blossoms which open first are the finest and most perfect and will, if pollinated, produce the finest fruits, and a special effort should be made to "set" these.

This question of self-sterility has not yet been entirely cleared up, but most of the well known cooking Plums are, as might be expected, self-fertile. Such are Victoria, Magnum Bonum, Pershore, Purple Egg, Czar, Monarch, Belle de Louvain, Giant Prune and Gisborne.

The choice Gage Plums are self-sterile, as are some not usually classed as Gages, but which are closely related, such as Coe's Golden Drop, Coe's Violet, Crimson Drop and, of course, Jefferson. The pollen of these four is said to be useless for fertilisation *inter se*, which is thought to be due to the fact that the other three are all sports from Golden Drop. Pond's Seedling is also self-sterile.

Frogmore Damson proves self-sterile and Farleigh Damson partially so, and it is well to ensure cross-pollination of Rivers' Early Prolific and Cox's Emperor.

Nearly all the best Cherries are quite self-sterile, except the Morello and the varieties Late Duke (not May Duke) and Flemish Red.

Of Apples the only important varieties which are really self-sterile are Cox's Orange Pippin, Lane's Prince Albert, Northern Greening, Gascoigne's Scarlet and Beauty of Bath; but it is well to ensure cross-pollination of Lady Sudeley, Worcester Pearmain and Bramley's Seedling. The last named, being an exceptionally robust grower, is seldom found in small gardens.

It was formerly thought that the notorious difficulty often found in setting Pear blossom was due to climatic conditions, but while the Pear blossom certainly is easily damaged by bad weather, there is no doubt that cross-pollination would in many instances effect a striking improvement in this regard.

AN INTERESTING SHOW AT THE ROYAL HORTICULTURAL SOCIETY'S HALL

A VERY interesting Show at Vincent Square on March 28 included something of everything seasonable in the floral line and everything was of very good quality. Although the Annual Daffodil Show is to be held a fortnight hence there were many good blooms on view. They were mostly of the large-flowered trumpet varieties and included quantities of richly coloured King Alfred, by Messrs. Carter and Co., and such as Alasnam, General Joffre, Princess Juliana and Mustapha in Messrs. Barr's fine exhibit. But here and in another instance the most interesting were unnamed seedlings.

Greenhouse Cyclamen were wonderfully good. Perfect plants with a great many flowers were shown by the St. George's Nursery Company, whose very best were Mrs. L. M. Graves, a brilliant crimson, and St. George, which has bright flowers and beautifully mottled leaves. Several baskets of the frilled Cyclamen were interesting and showy, but these, as well as many of the other present strains, have lost the graceful characteristic shape of the true Cyclamen which was present in Sweet Scented, shown by Messrs. Sutton and Sons with their excellent Cinerarias and Freesias. This Cyclamen is almost identical in appearance with the original *C. persicum*, and is deliciously fragrant.

From the flower-lover's point of view the best Freesias were the splendid pots of *F. Excelsior*, sent by F. C. Stoop, Esq., West Hall, Byfleet. These were exceedingly fragrant and may be termed a glorified *F. refracta alba* with a touch of primrose-yellow.

Among the various shrubs a large bush of *Rhododendron Ernest Gill*, from the Falmouth district, was pre-eminent. It is a glorious thing—large, perfect trusses of rich, glowing pink. These Himalayan hybrids, unfortunately, are not generally hardy, but they luxuriate in many favoured gardens along the western shores of Great Britain as well as in many parts of the South. Mr. Gill also had richly coloured blooms of *Rhododendron barbatum*, while Messrs. Cheal and Sons included the hardier *R. Jacksoni* in their collection of shrubs and alpinists. Some trusses of half-hardy *Rhododendrons* were shown by Mr. G. Reuthe, and among his uncommon shrubs were two small specimens of *Vaccinium Nummularia* and *Polygala rhodoptera*. His sprays of *Pieris japonica*, cut from thin woodland planting, had exceptionally white flowers.

Most glorious colour was provided by the *Azalea mollis*, shown by Messrs. R. and G. Cuthbert. The masses of bloom seem to vibrate with rich pink shades.

Chief among the many alpinists were the Saxifragas and these included *Saxifraga Russell Prichard*, a very good white of *Burscheriana* type; *S. Sundermanni*, *S. retusa*, a dainty little rosy purple; and *S. Stuartii*, with coloured, erect flower-stalks.

Forced Roses were especially beautiful on Mr. Hicks' stand and included the new *Madame Butterfly* with *Columbia* and *Premier*, two fragrant deep pink sorts. In Mr. Prince's exhibit there were masses of the old yellow *Banksian* and *Fortune's Yellow*.

A wonderful collection of *Dendrobiums* was included by Messrs. Sander in their gold medal exhibit of Orchids. Seldom have these decorative sorts been shown in such excellence. Among their rare Orchids was a plant of *Arachnanthe Cathcartii* St. Albans variety, which bears hooded, orange-lined flowers that have a curious swinging lip that sways on the slightest provocation.

Although not extensive, the fruit and vegetable exhibits were interesting and valuable. Sir Montagu Turner sent a collection of twenty-eight dishes of late-keeping Apples. Some of them were showing slight signs of shrivelling, but mostly they were firm and apparently crisp, while all were of ideal size and shape. The best sorts at this season seemed to be *Ribston Pippin*, *American Mother*, *Christmas Pearmain* and *Winter Ribston*. This excellent exhibit received a Hogg Memorial medal. The first, by the way, under the new rule that the Hogg medals are to be awarded solely to fruit exhibits and not to vegetables as well,

THE CRIMSON SEMI-SINGLE CLIMBING ROSE—H. C. CHANDLER.

as has been the case in the past. In future vegetable collections worthy of high honour will receive Knightian medals.

Seven baskets of *Doyenne du Comice* Pears, grown on the Rhodes Fruit Farm, South Africa, were on view. These were of very even shape though not yet ripe. The South African *Kelsey Plums* were probably the finest that have been seen in this country.

The first Cucumbers of the season at Vincent Square were on show in an exhibit by Messrs. Sutton and Sons, and this also included beautifully white *Broccoli Snow White*, one of the very best late sorts.

NEW AND RARE PLANTS.

Asparagus Lewisii.—In appearance this new decorative greenhouse variety suggests a cross

between *A. Sprengeri* and *A. plumosus*. The growths are long and graceful and the pale green branches are flattish. It might almost be said that this is an *Asparagus* trying to look like a climbing *Podocarpus*. It will no doubt be a useful plant for furnishing sprays of greenery for decorative uses. Award of merit to Messrs. J. Lewis and Son.

Eupatorium Rafillii.—This is a handsome greenhouse plant of uncommon appearance. The heart-shaped leaves are fully 5 ins. across, deep green, lustrous, and their sunken ribs give an attractive, crinkled effect. It belongs to the Natural Order Compositæ; the flower-heads are very numerous, spreading, and of reddish lilac colour, which is also prominent on the hairy stem and leaf stalks. A large group of splendidly grown plants of this species and *E. macrophyllum* was shown. The latter differs in having softer, paler leaves without the reddish-lilac colour on the stalks and in rather paler flowers. These *Eupatoriums* thrive best in rich soil and require abundant supplies of water during the growing season. Award of merit to Mr. A. Barclay Walker, Firfield, Weybridge.

Saxifraga Hybrida Gem.—There does not seem to be much to distinguish this variety from *S. Irvingii* other than that the flowers are a trifle paler. However, it is a very pretty little alpine plant and those on view were very free-flowering. Award of merit to Mr. Maurice Prichard.

Rose H. C. Chandler.—This semi-single rich crimson climber is very pleasing in form and if a good doer and free should be valuable for cut flower. It has excellent foliage. Shown by Mr. George Prince.

Scilla sibirica pallida.—As the name suggests, this is a pale variety of an old and valued spring flower. But it is rather too pale to be a welcome addition—the colour is a washed-out Cambridge

blue. Had it been several shades darker it would be much more attractive. Shown by Mr. C. G. van Tubergen.

Narcissus St. Bernard.—A large trumpet Daffodil. The perianth is of good yellow colour and the trumpet is of deeper tone with just a suggestion of orange. Its great attraction, however, is in the evenly fringed margin of the trumpet. Shown by Messrs. F. H. Chapman, Limited.

Freesia Apotheose.—A coloured *Freesia* of large size and good habit. The roundish blooms are fairly heavily flushed towards the edges with rosy purple. When seen in fair quantity, as was the case in Messrs. Sutton's exhibit, it is very attractive. Shown by Mr. C. G. van Tubergen.

Sophro-Lælio-Cattleya King George.—This multi-hybrid shows a great improvement in colour on its predecessors and is almost as bright and showy as some *Lælio-Cattleyas*. The sepals and

petals are of rosy-mauve colour with a golden shading. The rosy-purple lip has distinct lines running to the base. First-class certificate to Messrs. Flory and Black.

Odontoglossum Garnet.—A small plant bearing a spike of large, perfectly shaped flowers was shown.

bright rosy-mauve. Award of merit to Messrs. Sander and Son.

Apple John Standish.—During the autumn at several R.H.S. meetings, and at the Crystal Palace Empire Fruit Show this handsome Apple was shown in great quantity and thickly clustered

them; half-decayed leaves form a suitable drainage material. The compost when placed in the boxes should be made moderately firm, with a level surface and be watered about one hour before the seeds are sown. Do not immediately water the soil put on to cover the seeds. Sow the latter thinly, as any overcrowding would weaken the resultant seedlings.

CAULIFLOWERS AND CABBAGES.—Sow the seeds in boxes and cover them a quarter of an inch deep. Be very careful in regard to watering as the seedlings soon damp off. Transplant the latter when the first rough leaf has formed.

CELERY.—Frequently too many seeds are sown then the young seedlings get spoiled. Use a pot or pan for the Celery and a small addition of leaf-soil to the general compost. There must be more drainage material used too. Only put on a very thin layer of fine soil when covering the seeds; then place a square of glass on the seed vessel and a sheet of brown paper. If water is needed apply it by immersing the pot or pan to the rim. The first transplanting should take place when the seedlings are quite small. This sowing should constitute the maincrop one.

LETTUCES.—A splendid batch of young plants may be quickly raised in a frame. Here, again, sow thinly and transplant at an early stage of growth. Several small sowings at ten day intervals are better than one large sowing.

ONIONS AND LEEKS.—Young plants raised in heat should be transplanted in boxes or beds in the frame and gradually hardened prior to the final planting in their permanent quarters.

TOMATOES.—It is not safe to plant Tomatoes in the open air before the first week in June. But in the meantime the cultivator can bring on a nice lot of plants in his frame; they will be sturdy and not too tall. They may be grown in pots or boxes; I prefer pots. Use a small quantity of wood ashes and old mortar rubble in the compost and pot firmly.

VEGETABLE MARROWS AND CUCUMBERS.—The seeds of both must be sown in small pots. The compost should be light—half leaf-soil and half light loam. Use it in a medium state of moisture, and do not water from the top but immerse the pots to their rims in a vessel of water when more moisture is required. The same care must be taken when it is found necessary to repot these plants and as they are soon killed by frost cover the frame at night.

RADISHES AND MUSTARD AND CRESS may be quickly raised in a bed in a frame. Potatoes planted, with seeds of Radishes and Lettuce scattered thinly on the surface soil and raked in, will constitute three crops at one time in another frame.

OLD TIMER.

A NOVICE'S ROCK PLANT

WALLACE'S Saxifrage, a hybrid plant raised in Edinburgh a good many years ago, has established itself as a favourite flower with many cultivators of rock and border plants. It is one of the best of the whites among the "mossy" varieties, although it shares, in common with a considerable number of others, larger foliage than we feel justified in characterising by that term. However, it has beautiful leaves and, even when out of flower, a clump makes a handsome mound of green either in the rock garden or in the front of the border. The flowers, which are large for the section to which it belongs, are pure white, and a good plant with its wealth of bloom is a delightful sight. Saxifraga Wallacei is quite hardy and grows in most common soils, though light, gritty ones suit it best. It should not have too parched a position. A big plant looks remarkably well hanging from a crevice in the rockery or over a ledge.

SOMEWHAT IN THE WAY OF SAXIFRAGA IRVINGII, THE DELICATE PINK SAXIFRAGA × GEM.

The blooms are margined and tipped with clear white, but otherwise the petals are of rich reddish violet colour. The broad lip bears a large golden crest and is blotched in front with the petal colour. First-class certificate to Messrs. A. and J. McBean.

Dendrobium Perfection var. Gloria.—A particularly showy Dendrobium of *D. nobile* type. The sepals and petals are heavily flushed with

on branches to illustrate its heavy fruiting qualities. To this and its bright and attractive appearance must be added long keeping, for the bright red fruits were quite firm and of fresh appearance. Although the flavour is said by the experts to fall just short of first-rate, it is very pleasant eating, so that it appears to be a desirable variety. Award of merit to Messrs. Isaac House and Son.

RAISING EARLY VEGETABLES IN FRAMES

Many amateur gardeners use their frames for little else than preserving plants through the winter. Their utmost value is shown, however, at this season of the year.

UNDoubtedly the possessor of a garden frame has a considerable advantage over his neighbour who does not own one. A nice frame is an ornament to any garden, but as regards utility alone, a quite primitive frame is, practically, just as helpful.

The wooden frame, that may be moved at will from one position to another, is the most useful to the amateur cultivator, but one must not despise the fixed or permanent frame, whether it be made of turves, wood or bricks. Only in exceptional cases should the fixed frame be in any position other than one facing due south. For the bringing on of early crops in spring the south aspect is absolutely essential.

Seedlings and very young plants are dealt with in frames at this season of the year, and all such must be within a few inches of the glass, so as to keep them sturdy and strong. In two or three barrowloads of compost thousands of seedlings may be grown quite satisfactorily, while in a cold, clayey open border a large percentage of the best

of seeds may fail to germinate if sown very early. There is also this advantage that while the young plants are "coming on" in the frame, the cultivator is at liberty to deal with the soil in the garden, and thus bring it to a high state of cultivation and make it fit to receive the young plants in due course.

THE COMPOST.—Fibrous loam cut about six months ago—early last autumn—should form the body of the compost; to this must be added sweet leaf-soil and sufficient sand to render the whole porous. One peck of well rotted manure must be mixed with two bushels of the compost for the benefit of the young plants when they are first transplanted. No manure is needed in the soil for the seeds to be sown in. All the compost, when used, should be in a medium state of moisture. All seedlings and young plants may be grown in boxes, pots, pans or a bed in the frame. The average depth of the bed in the frame should be 6 ins. In boxes the soil should never be less than 3 ins. deep in addition to the drainage material. Boxes must have holes in

CORRESPONDENCE

A SELECTION OF SHRUBS.

IN common with the majority of people I find it necessary to study economy in my garden. In the old days it was mainly laid out for flower effects, but I am thinking of reducing the flower garden section and substituting shrubs. I should be much obliged if you could give me the names of say, four or five dozen of the leading species and their best varieties and some idea of their effect. The soil is chalk with a good deep soil above. I am quite aware that it is too late to put these in for the present season, but I should like to make plans as to what to do in the early autumn. A work on shrubs gives so enormous a number that it somewhat perplexes a modest man who is not an expert on the subject and whose room is limited—

it is just a selection of the best shrubs I am asking for.—H. E.

[The above topic seems to us to be of such interest to many readers on similar soils, that we invite those who have had experience of similar conditions to give their views.—ED.]

SAXIFRAGA OPPOSITIFOLIA AND CHIONODOXA.

I AM sending herewith two photographs. The first is of wild plants collected on the Welsh mountains a few years back and now established on a moraine in my rock garden. As will be seen, the Saxifragas are very much at home and flowering with an enthusiasm only equalled by that which the species displays in its native habitat.

A LITTLE COLONY OF THE GLORY OF THE SNOW—CHIONODOXA LUCILÆ.

A CORRESPONDENT'S MORAINE, SHOWING ROBUST TUFTS OF SAXIFRAGA OPPOSITIFOLIA.

For a time I endeavoured to grow these carmine blossoms in gritty loam, where they appeared in a somewhat desultory fashion, but since removal to the moraine the plants have spread so greatly as to endanger *Gentiana verna* and other choice tenants of the same bed of granite chippings. *Oppositifolia* is a Saxifrage of engaging habit. On some mornings its hue is changed to delicate pink beneath a film of hoarfrost or snow, but the blooms shine out again with undimmed brilliance as soon as the sun has melted the nightly crust. Moreover, it is not a small matter to have carmine flowers in really telling patches during the early days of March, and those borne upon British wildings. The *Chionodoxa* is another tiny flower which furnishes gallant colour out of doors when the year is but young. It possesses the desirable knack of multiplying itself almost indefinitely, but accomplishes that feat without becoming a nuisance to its neighbours. When the blooms have faded, the "grass" quickly dies down, and although the seedlings thrust up for a time like Lilliputian Onions, they too disappear and no more is seen of the "Glory of the Snow" until another March brings forth a fresh splash of bluest blue. The second photograph gives some idea of the freedom with which one of many small colonies of *Chionodoxa* is brightening a corner of my rock garden in its "off season."—R. H., *Stratford-on-Avon*.

A LITTLE SEEN ROCK PLANT.

I SHOULD like to warn the unsuspecting against *Calceolaria polyrhiza*, about which I see a note and pretty illustration in March 25 issue of THE GARDEN (p. 144). It is a fearful weed and runs about all over the place, producing in most soils an undue proportion of leaf to flower. It is perfectly hardy, but should only be planted where nothing better will grow.—M. F.

CALCEOLARIA POLYRHIZA may be little seen, but if it gets into ground it likes it runs a long way in a little time and it is quite possible you may wish that you had not seen it. I quite agree that the plant is both interesting and pretty, and it is quite hardy even in North-east Yorks. While not advising its exclusion from our gardens, I should impress on any contemplating procuring it that they do not place it in moraine, good sandy soil or peaty boggy ground if they have any plants they highly value anywhere near. Personally, I have spent many hours in removing it from positions where it had become a nuisance, and the only way to get it out is to take plants, soil and stones out from a considerable area.—T. A. L.

THE CHINKERICHEES.

IN the account of the fortnightly meeting of the R.H.S., appearing in THE GARDEN for January 28, there is, I think, a slight inaccuracy as regards *Ornithogalum lacteum*. It is stated that "there were some vases of *Ornithogalum lacteum* which were given their Zulu name of Chinkerichee." Chinkerichee is not a Zulu name for them, but a Dutch one and was, I believe, originally *tintermtjes*. Also the variety of *Ornithogalum* that is known out here as Chinkerichee is *O. thyrsoides*, not *lacteum*, as you state. Other names for the same plant are *Star of Bethlehem* and *violdtje*. Both the leaves and flowers of *O. thyrsoides* are poisonous to stock. There is a good description of the plant in Dr. Marloth's recently published "Flora of South Africa," Vol. iv, page 100.—J. ERIC STEWARD, *Empangeni, Zululand*.

NARCISSUS CERVANTES.

A NOTICE of this Daffodil appeared in THE GARDEN about Daffodil-time last year. I can only recall two remarks the writer made about it; the one was that it resembled Princeps somewhat, the other was that it was unusually floriferous. I had the pleasure of seeing a batch of fifty bulbs of it in bloom on January 13, which speaks of its early flowering qualities, as it was grown in a very moderate temperature. It certainly resembles Princeps, but it is hardly so large, either as regards height, breadth of foliage or size of flower. It is a clearer yellow than Princeps, the trumpet is more finely frilled, and altogether it is more refined than the old favourite. With regard to its free-flowering qualities, each bulb produced three or four blooms, but only one or two produced the promised five. The price from an Edinburgh firm was 22s. per hundred. When it comes down to half that price this will prove an acquisition for early forcing in quantity or for naturalising.—

CALEDONIA.

[There is no doubt that these smaller Daffodils are most useful for naturalising where space is strictly limited.—Ed.]

DROUGHT AND FERTILITY, AND OTHER MATTERS.

THE month of March on the Riviera has been genial and fine as a whole, though, of course, we have felt something of the cold fit we hear of elsewhere. The beauty of the spring flowers this year after the severe drought is more amazing than ever and proves once more how the aeration of the soil caused by long heat and drought acts as a fertiliser and stimulant when rain has fallen at last! The bloom on Waterer's Cherry, on the Pyrus (Malus) Scheideckeri, on Xanthoxeras sorbifolia, the Double Peaches, the Tenerife Broom, the great white Buddleia asiatica is more beautiful and more abundant than ever. The flowering Aloes, Salm-Dyckiana, pseudo-ferox and others are twice as gorgeous as usual, and the wild Anemones (Hortensis) and Soleil or Annulata carpet the bottom of the valley with a blaze of colour that seemed impossible two months ago. Judging by the growth of the Roses also, the long drought and rest must have acted as a stimulant, and the bloom next month must be extra fine. Lithospermum rosamarinifolium is more abundantly blue than I ever saw it, and Anchusa myosotidiflora surprises and enchants those who seek for the blue sky repeated on the ground. What a delightful plant it is for the semi-wild garden! Perhaps a big bush of Citrus trifoliata, bristling with thorns and great white flowers, next to a tall post which is draped with Jasminum primulinum with sprays of flowers that hang in yard-long festoons, is one of the most admired of spring delights. There is a pretty new hybrid Cineraria between C. aurita and the common annual greenhouse Cineraria that demands notice. It is dwarf and elegant in growth and foliage, and the colours of the flowers varied so that if it partakes of the semi-wooded and perennial qualities of C. aurita it will be a real gem to gardeners in England as well as on this coast. The pale yellow form of Iris olbiensis is particularly good just now; it is earlier than the germanica forms that wait till the Banksian Roses and the Tree Paeonies are fully out; it is particularly pretty in combination with the peach-pink Tulipa saxatilis that is so free-flowering and so happy on this coast. There was a flower show at Nice the other day, but the flowers in the windows of the best florists were much finer than those shown! I do not know where the blame lies, but such a fiasco as this show proved to be should not be repeated. To those who know the glories

of a London or a Paris show this travesty of all that is interesting and beautiful should not occur "on this coast."—E. H. WOODALL.

GALANTHUS IKARIE.

THE following interesting observations on this Snowdrop are taken from a letter sent by Mr. Henry Elwes to Sir Frederick Moore: "I read your wife's note on Snowdrops in THE GARDEN of March 18, and it set me to look up Galanthus Ikarie (of Baker), about which I have

long had doubts. I now find it is probably identical with G. græcus (orph. in litt), discovered by him in Chirs on a mountain of about the same height (1,000 metres) as Nikaria, which is only thirty miles north of it, and this probably accounts for its hardiness in comparison with other Greek Snowdrops, which all die out with me. Bonner says that G. græcus (which he first described) is intermediate between Elwesii and nivalis; and as the characters on which Baker relies are very variable, I had always doubted the specific position of G. Ikarie."—W. PHYLIS MOORE, Glasnevin.

THE TREATMENT OF SEEDLING TOMATOES

Insufficient attention is often paid to the Tomato. If the best results are to be obtained, considerable care must be taken with their cultivation, especially in the seedling stages.

SUPPOSING the seeds to have been sown fairly early, the plants should now be ready for potting up into zin. pots. The very early batches will, of course, before now be good plants in "sixties." We will assume, then, that the seeds have been sown thinly and that the resultant plantlets have been allowed abundance of light and a sufficiency of heat, and that they have, at any rate, reached the "brairding" stage—that is, they are now forming their first true leaves. Their subsequent culture up to the time that the first trusses show is as follows:

Brairding is with all seedlings a time of trial, and special care must be taken of the plants until it is safely through. They must never, of course, be allowed to become dust dry, nor, on the other hand, must they ever be watered until water is really required. The water given must always be as warm as, or preferably a few degrees warmer than, the temperature of the house in which they are growing, and it should, if any way this is possible, be soft. Surprisingly soon after brairding has taken place both leaves and roots will have need of more room if the plants are to grow as sturdily and healthily as they should. They should not be allowed in the least to draw one another, but should be potted up singly into zin. pots. The compost will be similar in character to that recommended for the seed bed, but, if broken finely, it need not be riddled, as the roots have not again to be separated, and the rougher fibrous portions can be used for the bottoms of the pots. The compost mixed, it should be taken into the house where the plants are growing a few days before it will be required, as should the necessary number of pots, and left there. If in a heap, the compost should be turned a few times, so that at potting time it may approximate to the temperature of the house. This is very important. It should be unnecessary to state that at all stages of growth, but particularly as long as the plants will have to be transplanted, the pots should be scrupulously clean, more especially inside, and quite dry at potting time. Pots all ready and coke-dust for drainage, and the nicely warmed compost placed to hand; make sure before commencing operations that the soil in the seedling boxes is not too dry for the rootlets to come apart easily. To prevent such a *contretemps* it is better to water them a few hours beforehand, even though they seem fairly moist already. Now lifting the box (or pan) of seedlings at an angle of 45° to the horizontal, tap it fairly sharply (not too sharply or disaster may ensue!) on the staging, when, if the blow was sharp enough, a crack wide enough for the fingers will be opened at the end of the box. With the aid of the fingers, or of the fingers

and a label inserted at the side of the box, a chunk of the little plants will come away. This little clump of plants should be taken in both hands and gently drawn, not forced, apart, the two clumps so formed being redivided until the plants are singled. On top of the small coke in the bottom of the pots place an inch or so of rough compost, then a sprinkling of the fine soil. Next put in the little plant, working the fine compost to it, but not ramming too hard nor tightening too much at the collar, as if the plant be bruised there it will die. A good deal of the tightening up is done by tapping the pot rather gently on the barrow, staging or portable potting bench. The absolute novice will find that to do it properly repotting (including the singling) is rather a tiresome job, but *experientia docet*, and it is surprising how many plants a skilled man will pot up in an hour, taking all the precaution mentioned. Though the days are longer now and light is now quite good, it is still very necessary to keep the plants as near the roof glass as possible. Glass-houses vary greatly in construction, but with a little contrivance this can always be managed. In many cases a false stage can be erected with boards and flower-pots nearer to the glass, or the pots may be packed in seed-trays and stood on a shelf.

Watering must at first be done carefully. It will not do to water the whole batch at once, willy-nilly, but as the pots get fairly full of root a good deal will be needed, and on bright days they had better all have a good soaking in the morning and careful inspection later in the day. As soon as the pots are full of root and before the plants show the smallest symptoms of getting stunted they should be retransplanted. If cultivation has been properly managed to date, the young plants should be from 7ins. to 10ins. high, according to variety, almost as like as peas in a pod, nearly or quite as wide as high, and they should still retain their seed leaves. That is not to say that plants need be rejected or thrown away because they have lost these, only that something has not been just right in the cultivation if they have. At this time the first truss of bloom should be fairly visible near the growing point of the plant. The seedling plants have at this time reached the parting of the ways, their disposal now depending on the method of cultivation finally to be adopted. If they are to be planted in the floor of a greenhouse, which is, where circumstances permit, the most economical and productive method, it will be found easiest to plant them direct in their permanent quarters—easiest and, where the space is free and the house can be adequately heated, best. At this stage of their development we will for the present leave them.

THE GREAT WHITE TREE POPPIES

THE present is an excellent season to plant out those beautiful Californian Poppies, *Romneya Coulteri* and *R. trichocalyx*, which are, especially until established, not over hardy. There will no doubt be a large demand for plants this season owing to the extraordinarily fine display given by both species last year. The protection of a south or south-west wall is generally advised for these shrubs, if shrubs they are, but if the soil is well drained they succeed quite well in all but the bleakest localities, in the open border so that the crowns be covered in winter with a few inches of fine ashes. The difference in appearance between *R. Coulteri* and *R. trichocalyx* is very slight, consisting almost entirely in the presence of bristly hairs on the calyx of *R. trichocalyx*. The latter species is, according to Bean's "Trees and Shrubs Hardy in the British Isles," harder than the better

propagates *Gypsophila paniculata* or *Anchusa italica*, taking care to place the end of the root which was nearest to the crown of the plant to the top. July or August is probably the best time to carry out this work, but it may be done even in winter.

Plants of *Romneya* from the open ground are useless for transplanting though, as shown, valuable for propagation. A strong plant in a 6in. pot is well worth the extra money always charged for older and larger specimens, as it has every opportunity of getting well established the first season. R. G.

PILLAR AND ROOF PLANTS

Some greenhouses and conservatories are unduly darkened by climbing plants, while others are left, year after year, quite bare. There is a happy medium: if this were more often sought out there would be less need for the artificial shading of structures in summer time.

A JUDICIOUS selection of climbers should be made to suit greenhouses of various sizes. The large-leaved, strong-growing *Habrothamnus elegans*, for example, is quite unsuitable for a small house, as it would unduly shade the plants underneath. Some of the *Jasminums*, again, would not afford sufficient shade in a large structure, and so on. There are a few species, notably *Bougainvillea glabra* and *Plumbago capensis*, that are suitable for practically all kinds of houses, as they may be pruned and restricted to really small spaces.

Where there is a position suitable for a border, even a narrow one, the plants may be planted out permanently; but there is not this convenience in many structures, so that use must be made of large flower-pots and boxes. At this season of the year the climbers may be purchased in pots and transferred forthwith to the border or the box.

In every case good drainage is essential, and this is ensured by using broken bricks, covered with whole turves, in the borders and nice clean crocks in the pots and boxes prior to putting in the compost.

The plants here enumerated are dealt with in detail in *THE GARDEN* at different seasons, so that it is unnecessary for me to give seasonal hints in this brief article. The main thing now is to procure the plants and

plant them. When judiciously employed, climbing and pillar plants have the effect of adding size to the structure and giving it a sub-tropical appearance. Among the better kinds, one must first name *Bougainvillea glabra*. It should be trained similarly to the Grape vine; the side shoots are cut back severely in the winter; the new shoots grow rapidly, and, if some of them are allowed to depend gracefully from the roof, the general effect is very beautiful when the flowers are opening freely. *Plumbago capensis* and the white variety should be treated in a similar way.

Clematis indivisa lobata has dark green, lovely foliage and white flowers. The shoots grow rapidly, are suitable for training to wires over the path, and, when the flowers have faded, the leaves form a welcome shade. The plant is easily grown in good loam and rotted manure.

Cobæa scandens and *C. scandens variegata* are among the quickest growing climbers we have for the greenhouse. A mixture of loam, leaf-soil and sand suits these plants, which should be planted in large pots for small structures. They look graceful trained up a pillar and then under the roof-glass, not too stiffly, especially in a large house; the loose ends of shoots should depend gracefully from the roof wires.

Heliotropes, *Fuchsias* and Ivy-leaved *Pelargoniums* are suitable for covering pillars, and their beauty is enhanced if the leading branches are allowed to cover, in addition, a few square feet of the roof.

As already stated, *Bignonias* and *Habrothamnus* are only suitable for large greenhouses and conservatories. The plants should be grown in good loam, but not in a rich one, to which organic manure has been added. During the summer time the *Bignonia* should be freely syringed, except when it is in bloom. The syringing is necessary, so on this account the plant should be grown where the syringing will not damage flowering plants underneath. The *Habrothamnus* must not be syringed. The plant may be controlled in growth by pinching the young shoots and by judicious pruning in spring.

On a fairly high roof *Taesonias Van-Volkemii* looks charming, as then the full beauty of the depending flowers on their long, slender stems can be seen. Use a similar compost to that suitable for *Clematises*—not too light nor too heavy.

The *Sollyas* are lovely plants for furnishing pillars; the flowers of *S. heterophylla* and *S. linearis* are blue and very attractive. When not in bloom syringe the plants in the summer, and maintain the compost of loam, peat and sand in a moist condition; in the winter keep the border rather dry. *Kennedias* should be similarly treated; *K. monophylla*, purple, and *K. Marryattæ*, scarlet, are charming varieties.

In greenhouses with northern, north-western or north-eastern aspects roof plants must not be employed too liberally, especially if flowering plants are to be grown beneath; but *Ferns* and *Palms* always thrive well in such structures.

FORTHCOMING EVENTS.

April 10.—United Horticultural Benefit and Provident Society's Meeting.

April 11.—Royal Horticultural Society's Daffodil Show (two days). Informal discussion on "Plants in Flower" at 5 p.m. on the first day.

April 12.—East Anglian Horticultural Society's Meeting. Sheffield Chrysanthemum Society's Meeting.

THE EVER-GRACEFUL ROMNEYA COULTERI.

known species, but the writer cannot confirm this from his own experience, though it would seem to be rather freer to flower in unfavourable seasons.

Once established, both species cover a great deal of ground, spreading quite rapidly underground, and it is possible to strike the young outlying shoots in a little heat when they are a few inches high, giving them similar treatment to that usually afforded to the herbaceous *Phloxes*. They are, however, much more difficult to root. The most effective method of propagation is to lift an old plant and cut up the thick fleshy roots into 2in. lengths and plunge them to the tops in sharp sand, just as one

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cardoons.—Seeds should be sown now, either in trenches of good soil, prepared in the manner as for Celery, or in pots in a frame, and the seedlings transplanted later. Place several seeds in a pot, eventually thinning the seedlings and leaving one in each pot. If sown directly in the trenches place several seeds at a distance of 12 ins. or 14 ins. apart and thin out, leaving the strongest plant. The Cardoon is a plant that appreciates an open position and good, rich soil and should be well supplied with water.

Salsafy.—This Parsnip-like root can be sown where it is to mature in drills a foot or 15 ins. apart, and the seedlings should be thinned out, leaving them 6 ins. to 8 ins. apart.

Scorzonera.—Seeds of this vegetable may be sown now. The cultural treatment as given above for Salsafy will suit this plant.

Seed-sowing.—If not already sown the main-crop of Carrots should now be got in. Carrots delight in a light, sandy loam, in which medium the long, tapering roots easily penetrate. On heavy land stump-rooted varieties should be used for preference. Draw the drills a foot to 15 ins. apart. Sow, as required, small beds of Radishes, Mustard and Cress on a warm border, and place handlights over them, if possible.

General Work.—Continue to plant out Cauliflowers, etc., which have been raised under glass and pricked out and grown on in boxes in frames. Lettuce should also be planted in frames and on a warm border outside in quantity, so as to keep up a supply. Seeds of this useful salad may be sown thinly in drills on the top of Celery trenches or between the rows of young Strawberry plants which have not made much growth. If inconvenient to do this they may be sown somewhat thickly in drills and transplanted in good time.

Early Celery.—See that the young plants that have been pricked out in boxes or on a mild hot-bed in a frame are carefully watered and ventilated to encourage the development of strong, sturdy plants. The seeds to form the main batch should be sown at once, and a most suitable place for this sowing would be in a frame having a few inches of light, rich soil in it on a declining hot-bed.

The Flower Garden.

Hardy Ferns.—The removal of all dead fronds and any accumulation of weeds or rubbish among these should now be seen to, taking care while carrying out the work that the young unfolding leaves do not get damaged. After lightly forking over the ground among the plants, apply a top-dressing of decayed leaf-soil.

Border Violets.—Where a border can be spared for these, either in the flower garden or kitchen garden, the flowers come in most useful as a follow-on to those grown in frames. Should an increase of stock be necessary, this can quickly be accomplished now by taking off the young growths as cuttings and inserting them in light, sandy soil in cold frames. Keep the frames somewhat close and shady until roots are formed, then gradually harden and disperse with the lights until the planting-out can be done.

The Hardy Fruit Garden.

Protecting Fruit Blossom.—By the aid of tiffany blinds or a double thickness of netting much may be done to try to save the blossom on early fruit trees growing against walls and buildings, but upon trees in the open it becomes a difficult matter to cope with. Where it is essential to protect the flowers upon bush or pyramid trees in the open, a few stout stakes of suitable height should be driven in and thin tiffany or netting tied to them. Even if only placed on the north and east sides of the tree, it is surprising what protection this affords.

Fruit Under Glass.

Melons.—Give regular attention to the stopping and tying of these plants in the early house. The side shoots should be pinched at the first or second leaf beyond a fruit where formed. Shoots not showing for fruit should be pinched at the first leaf, which generally encourages the laterals to carry fruit. The number of fruits for each plant to carry may be governed to some extent by the requirements, but, generally, for early work two or three will be found sufficient. Where possible, endeavour to fertilise a sufficient number of blossoms the same morning, for by doing this

the young fruits will grow away evenly together. It will be found beneficial to keep a somewhat drier atmosphere during the flowering period, but immediately that is over an abundance of moisture, atmospherically as well as at the roots, should be maintained. Should any top-dressing of the border be necessary, it should be warmed before applying and should consist of good fibrous loam and old Mushroom bed; this should be placed evenly and firmly over the bed. During the growing stages the utmost use should always be made of sun-heat by the early closing of the house.

H. TURNER

(Gardener to the Duke of Northumberland),
Albany Park Gardens Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Salsafy.—Sow seed of this serviceable winter vegetable now. Salsafy revels in light, loamy soil which has not been recently manured. Freshly manured land tends towards forked and scraggy roots. The site of the previous season's Celery trenches will suit admirably. Sow in shallow drills 18 ins. apart, and thin out the plants to 6 ins. apart in the row.

Peas.—A good sowing of marrowfat varieties should now be made. Suitable sorts are Duke of Albany, Peerless Marrowfat and Telephone. Stake earlier sowings immediately they show through the ground, as this affords the plants a certain amount of shelter should cold weather set in.

Cabbages.—Plant out batches raised from early sowings to succeed the autumn-planted lot. Small growing sorts, such as Ellam's Early and Flower of Spring, may be planted fairly close, 15 ins. either way being ample space.

Transplanting Autumn-sown Onions.—In districts where autumn-sown Onions can be successfully grown they should now be transplanted, allowing 12 ins. between the rows and 8 ins. between the plants. This crop proves valuable for early use and, when judiciously harvested, may be kept in usable condition for a good part of the winter.

Tomatoes.—Early sowings will now be ready for transferring to their fruiting quarters. If planting in borders, allow ample space for the development of the plants. Overcrowding among Tomatoes, as with most plants, is one of the chief causes of failure. Plant deeply and firmly in a compost of mellow loam with a liberal sprinkling of wood-ash added. Refrain from using manure until the first and second trusses are well set, and always aim to have firm and sturdy growth.

Cucumbers.—Maintain a warm, humid atmosphere in pits where the plants are in bearing, and assist with liquid manure from the byre. Thin out all superfluous growths, and stop the leading vines when the allotted space has been covered. Sow again for successional batches and to provide plants for planting out in frames about the middle of May. Sow the seed singly in 3 in. pots, and germinate in a warm pit.

General Work.—Clear off all spent winter vegetables, and hit the remainder of the Leek crop, heeling them in on a shady border. Afterwards manure and dig the ground in preparation for other crops. Prick out into frames seedlings from early sowings of Cabbage and Cauliflowers. These will provide well grown plants for mid-season crops. Brussels Sprouts should also be treated in like manner. Onions growing in boxes for planting out towards the end of the month should be gradually hardened off by allowing ample ventilation on the frames during fine weather. Keep protecting material at hand, as sharp and sudden frosts are common in the North during April.

Fruit Under Glass.

Vines.—In the earliest houses thinning will now require attention, and this important work should be pushed forward as speedily as possible. When thinning, bear in mind that the large berried sorts will naturally require more room than medium-sized sorts. Allow for enough berries being left so that when they swell to their full size the bunch shall be firm enough to hold itself in shape without being overcrowded. Give the Vine border a good watering with liquid manure a few days after thinning is completed.

The Hardy Fruit Garden.

Grafting Fruit Trees.—Where this work is to be done no time should be lost in making the

necessary preparations, as it is only now, when the sap commences to rise, that a satisfactory and speedy union between stock and scion may be made. Trees that were headed back during the winter pruning should be cut back a few inches further now that the sap is rising, so that the grafts may be fixed in sound bark. The grafts should be from 6 ins. to 8 ins. long, leaving three or four buds on the upper portion. In private gardens wedge grafting is favoured for the larger trees and whip grafting for young stock. See that the bark of the scion and stock fits closely, and secure with broad raffia, thoroughly smearing over with grafting wax.

The Flower Garden.

Nepeta Mussini.—Apart from the delightful soft grey of its foliage and charming lavender flower spikes, its lengthy season of flowering adds greatly to the popularity of this adaptable perennial. Where it is desirable to increase the stock, the plants should now be lifted and divided into small portions, placing them right away into their new flowering quarters. They will grow and flower freely in shady parts of the garden where other plants fail.

Pricking Out Seedlings.—This work will now occupy a good deal of time, but it must be carried through before the plants become drawn and weakly. A wise precaution is to have the necessary boxes or frames filled with a suitable compost, all ready for the various seedlings immediately they are of a suitable size to prick out.

Violas.—Plant out these at the first opportunity, as they do best when well established before the hot weather sets in. Violas enjoy a cool root-run and flower profusely if the ground has been enriched with well decayed manure.

JAMES MCGRAN

(Gardener to Sir Henry H. Holdsworth, Bart.),
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Rhododendrons.—There are many fine greenhouse Rhododendrons which at one time were very popular, but too seldom seen at the present day. This is rather surprising, as all the Edgeworthii hybrids are very fragrant. Grown in pots they are rather straggling in habit, unless carefully trained and pruned. They are, however, excellent for planting out in a cool conservatory, where they should be placed in shallow borders. Plant in a mixture of sandy loam and peat, and the plants will soon make fine large specimens. Most of these plants are easily propagated by means of cuttings, using young wood that is just firm enough to prevent damping. The cuttings may be rooted under quite cool conditions, but if it is possible to place them in a case with slight bottom-heat they root much more quickly. This mode of propagation applies to all the greenhouse Rhododendrons or Azaleas. Some of the best species and varieties are R. Edgeworthii, formosum (of which there are several varieties, the variety Gibsonii being commonly grown), Lady Alice Fitzwilliam, fragrantissimum, sesterianum, Forsterianum, Countess of Haddington and Veitchii. All these have been popular for many years. The many beautiful Javanese Rhododendrons, in a large variety of colours, are easily propagated by means of cuttings, and where a collector is grown, flowers may be had more or less all the year round. If they have a fault it is their rather straggling habit, but this can to a great extent be corrected by judicious tying and pruning. They are generally supposed to require a fairly high temperature, but I find they do quite well planted out in an ordinary conservatory.

Lilium sulphureum.—This beautiful and stately Lily only succeeds outdoors in the south-west. Planted out in a bed of good soil, along with shrubs, in a cool conservatory I have known it live for many years, and, when growing strongly, the stems may attain a height of anything from 6 ft. to 8 ft. Many fine Liliums that are uncertain outdoors should be tried indoors, planted out in a cool house, preferably among beds of shrubs, as the latter give the needful shade at the root; also the roots of the shrubs help to keep the soil in good mechanical condition. Lilium nepalense, which is not generally a success outdoors, should be grown under the above conditions. Liliums grown in pots and plunged in ashes or leaf-soil should, as they show signs of growth, be removed from the plunging material and stood in cold frames or in a cool house; or they may be left outdoors, plunged in ashes at the foot of a sheltered wall. All stem-rooting Liliums should be top-dressed as they require it.

Your Opportunity!

Government Disposal "Material" invaluable for
**LIGHT CONSTRUCTION
 WORK**

Supply of these Fruit and Vegetable Storage Trays is now limited. Perhaps you have no immediate storage problem, but show you should order with eye to the future. Once our present stock is exhausted, you will be quite unable to obtain anything like the value. **LIGHT CONSTRUCTION WORK.** These trays, strong and well made, are ideal for Potato Sprouting, Greenhouse Racks, Garden Benches, Summer Houses, and undoubtedly there are other uses you can find for them. At such a price they form one of the finest investments ever offered to readers of this journal.

Mrs. Pym's Famous Plants
GOOD AND CHEAP.

SPECIAL OFFER of good, strong, sturdy plants. Should be planted now for success: Half lots same rate. All post free or carriage paid, passenger train. Cash with order. Catalogue free.

4d. extra for orders under 3s.

Strong vegetable plants, wintered in open: Leeks, Tripoli Onions, Pickling Cabbage, Cos and Cabbage Lettuce, Perpetua Spinach, 100, 1/9. Rhubarb, best named, red, 6, 1/6. Sage, Thyme, Mint, Marjoram, 6, 1/6. Parsley, best curled, 12, 1/4. Asparagus, colossal and giant, strong 2 year old roots, 50, 4/6; 100, 7/6.

HARDY PERENNIALS, very strong, transplanted, to flower this year. Best strains procurable. Achillea, Perry's double white, 3, 1/6. Aconitum, handsome new large flowering, named, 3, 1/6. Aster alpinus, rare lovely rockery plants, 2, 1/4. Agrostemma, crimson, 6, 1/6. Alstromeria, Peruvian Flame Flower, 2, 1/4. Alyssum, gold dust, 6, 1/6. Alpine Wallflower, 20, 1/6. Alpine Pinks, 12, 1/9. Anchusa italica, Dropmore, lovely blue, 6, 1/9; Anchusa angustifolia, true deep blue, 6, 1/6. Anemone japonica, pink or white, 2, 1/4. Anemone pulsatilla, a most beautiful spring flowering hardy perennial followed by handsome fruit, 2, 1/4. Anthemis montana, 6, 1/9. Aquilegia, Kelway's hybrids, 6, 1/4. Arabis, double white, 6, 1/6. Aubrietia, rich purple, 6, 1/6. Auriculas, lovely alpine varieties, 4, 1/6. Antirrhinums, bushy plants, lovely new colours, 6, 1/4. Brompton Stocks, large, year old, 6, 1/6. Christmas Roses, large crowns, 1/4 each. Campanula, blue or white dwarf or tall, 3, 1/4. Campanula pyramidalis, 2 year old, 3, 1/6. Canterbury Bells, single, blue, pink, mauve, white, or Dean's grand hybrids, 12, 1/9; double, 6, 1/6. Candytuft, perennial, 3, 1/6. Carnations, good borer, 6, 1/6; separate colours, white, yellow, crimson, scarlet, 6, 1/9; Grenadin, lovely double scarlet, 6, 1/9. Centaurea montana, blue, white or rosy mauve, 6, 1/6. Chrysanthemums, strong rooted cuttings, best early, mid and late, all colours, separate or mixed, 6, 1/6. Cerastium, 12, 1/9. Cistus (Rock Rose), 6, 1/9. Coreopsis grandiflora, 6, 1/4. Cornflower, Kelway's blue, 12, 1/6. Daisies, new enormous double blooms, red or white, splendid for bedding, 12, 1/4; mixed, 20, 1/6. Delphinium, best named, large 2 year old, 2, 1/9. Delphiniums, grand large flowering hybrids, light or dark blue, year old plants, 3, 1/6. Dianthus, Kelway's lovely double or single, 12, 1/6. Dianthus, creeping, bright pink, 6, 1/4. Dielytra, Bleeding Heart, large roots, 1, 1/4. Erigeron (stebastis), mauve Marguerite, 4, 1/6. Erysimum, Golden Gem, 20, 1/6. Forget-me-nots, best dwarf blue perennial varieties, 12, 1/4. Funkia subcordata grandiflora alba (Corn Lily), most lovely, pure white, exquisitely fragrant flowering, prized for cutting, very handsome, large glaucous green leaves, 3, 1/6. Gaillardia grandiflora, 6, 1/4. Galega (Goat's Rue), 6, 1/6. Galadiolus, best large flowering, 12, 1/9. Geum Mrs. Bradshaw, large double scarlet, 2, 1/6. Galtionia, hardy white Lily, long stout stems covered with waxy bells, 2, 1/4. Gypsophila paniculata, 6, 1/6. Gypsophila, dwarf, 12, 1/9. Heuchera, scarlet, 4, 1/4. Hollyhocks, lovely colours, single, 6, 1/6; double, 4, 1/6. Honesty, crimson and white, 6, 1/4. Iceland Poppies, Excelsior strain, 6, 1/4. Iris germanica, separate colours, mauve, white, blue, purple, yellow, 3, 1/6. Iris, large flag, splendid colours, 6, 1/6. Kniphofia, handsome Torch Lily, 3, 1/6. Linum (Blue Flax), 12, 1/9. Lily of the Valley, giant variety, soon flower, 6, 1/6. Hardy Lilies, large, orange red and tawny, 3, 1/6. Linaria dalmatica, 6, 1/6. Lobelia cardinalis, 4, 1/6. Lupinus polyphyllus, pink, white, blue, 6, 1/6; mixed, 12, 1/9. Lupin, tree, yellow or white, 3, 1/6. Lychnis, scarlet chalcidonia or Salmon Queen, 6, 1/6. Malva, bright pink, 6, 1/6. Monarda (Bergamot), Cambridge scarlet, 2, 1/4. Montbretias, new varieties, 12, 1/6. CEnothera Macrocarpa, beautiful dwarf Evening Primrose, masses of large yellow bloom, 3, 1/6. Pansies, best large flowering and separate colours for bedding, 12, 1/6. Papaver pilsosum, rich orange blooms, 6, 1/6. Phlox, best large flowering, mixed, 4, 1/6. Phlox, best large flowering, all colours, 3, 1/6. Paeonies, separate colours, 2, 1/6. Paeonies, mixed, 3, 1/6. Poppy, Oriental Queen, enormous blooms, 6, 1/6. Phealie (Giant Cape Gooseberry), 6, 1/6. Pinks, coloured garden, 12, 1/9. Pinks, double white, 6, 1/6. Potentilla, double-crimson, 6, 1/6. Primulae, hardly assorted, for succession of bloom, 6, 1/6. Pentstemon, scarlet, Southgate Gem and grand Excelsior strain, 6, 1/9; smaller good plants, 6, 1/4. Pyrethrum, Kelway's, 4, 1/6. Pyrethrum James Kelway, large scarlet, 2, 1/4. Pyrethrum, double red, white, pink, 3, 1/6. Rose Campion, bright crimson, 6, 1/4.

Rudbeckia speciosa, 3, 1/6. Saponaria, pink rockery, 6, 1/6. Scabious, Sweet, 12, 1/9. Scabious caucasica, large hairy, 1 year plants, 3, 1/6. Silene compacta, pink, 15, 1/6. Stachys (Lamb's Wool), 6, 1/4. Star of Bethlehem, 6, 1/6. Statice (Sea Lavender), 3, 1/6. Sweet Rocket, 12, 1/6. Sweet William, double and single mixed, lovely colours, 12, 1/6. Sweet William, lovely scarlet, pink, and Crimson Beauty, 6, 1/4. Thistle Queen of Scots, 3, 1/6. Thalictrum (hardy Maidenhair), 4, 1/6. Tritoma (Red-hot Poker), 3, 1/6. Tussilago (hardy winter Heliotrope), 3, 1/6. Verbascum, tall, 6, 1/6. Valerian, crimson, 6, 1/6. Veronica, blue, 4, 1/4. Viola, separate colours, for bedding, and good mixed, 12, 1/6. Viola cornuta, mauve, purple, blue and white, Queen, masses of bloom for rockery, etc., 12, 1/9. Sunflowers, new red, 3, 1/6. Aster, Michalinas Daisy, good named sorts, 3, 1/6. Achillea, very bright Crimson Queen, 3, 1/6. Antirrhinums, strong autumn sown (not transplanted), 12, 1/6. Centaurea dealbata, lovely large fringed pink flowers, pretty silvery foliage, 3, 1/6. Chinese Pinks, very showy, 6, 1/6. Campanula maerantha, tall, large mauve blooms, 3, 1/6. Chelone barbata, coral red lobster flower, 3, 1/6. Crucianella, lovely for rockery, dense heads of pink bloom, 6, 1/6. Dianthus, rock, dwarf, lovely colours for rockery, 6, 1/6. Hypericum (St. John's Wort or Rose of Sharon), large yellow blooms, evergreen glossy foliage, 4, 1/6. Incarvillea Delavayi grandiflora, beautiful large Gloxinia-like blooms, handsome foliage, 3, 1/6. Inula glandulosa, large golden yellow flowers, bold and handsome, 3, 1/6. Lavender bushes, fragrant old English, 3, 1/6. Japanese Pinks, very pretty colours, 6, 1/4. Pyrethrum Queen Mary, large double rose pink, 2, 1/4. Oriental Poppies, very large salmon blooms, large plants, 2, 1/6. Shirley Poppies, beautiful art shades, 6, 1/4. Paney Coquette de Poisey, beautiful pale mauve, for bedding, 12, 1/10. The following Primulas are quite hardy, thrive best in damp situations, and do well in pots: Primula japonica, 4, 1/6. P. cortusoides, bright rosy purple, 4, 1/6. P. Bullayana, beautiful shades, 3, 1/6. P. pulverulenta, rich colours, 4, 1/6. P. denticulata cashmiriana, large heads, light purple, 3, 1/6. Rudbeckia Golden Ball, double, 3, 1/6. Perennial Sunflower, Miss Mellish, etc., 6, 1/6. Saxifraga, mossy, white, pink, crimson, 4, 1/4. Rock Roses, trails of lovely coloured flowers, rockery gem, 6, 1/9. Cheiranthus, Siberian Wallflower, masses of bloom all summer, 20, 1/6.

Strong transplanted plants for cool houses: Agapanthus, large blue African Lily, year old plants, 3, 1/4. Agathaea (blue Marguerite), 4, 1/4. Asparagus Fern, erect or trailing, 4, 1/4. Begonias, scarlet, crimson or Salmon Queen, evergreen, perpetual flowering, 6, 1/6. Auriculae, grand large flowering, show, 4, 1/6. Cannas, Crozy's splendid hybrids, large 2 year old, 3, 1/6; 1 year, 4, 1/4. Cinerarias, exhibition and stellata, 6, 1/6. Eucalyptus, 4, 1/4. Francoa (Bridal Wreath), 6, 1/6. Heliotrope, very large heads, fragrant bloom, 4, 1/4. Lobelia cardinalis Queen Victoria, 4, 1/4. Nicotiana, white or crimson Tobacco, 4, 1/4. Primula nialacoides (rosy-lilac), 6, 1/6. Primula obconica, new, giant, lovely colours, 4, 1/4. Rehmannia, pink trumpet, 3, 1/6. Salvia, Scarlet Zurich, 4, 1/4. Salvia, scarlet cocinea, 6, 1/4. Saxifraga Mother of Thousands, trailing, 4, 1/4. Streptocarpus, lovely Cape Primrose, large blooms, lovely colours, 4, 1/4. Aralia (Fig Palm), 2, 1/4. Celeia critica, pretty spikes of yellow and mauve flowers, 4, 1/4. Cyclamen, choice new sorts, 3, 1/9. Fuchsias, choice varieties, 3, 1/6. Marguerites, large yellow and Covent Garden White, 4, 1/4. Smilax, trailing, 3, 1/4. Cordyline Dracena indivisa Veitchii, handsome hardy palm, strong 3 year old, about 9ins., 2, 1/6. Schizanthus, butterfly flower, lovely new large flowering hybrids, 6, 1, 4. Tomatoes, strong, transplanted, best sorts, 6, 1/6. Hardy Climbers. Ampelopsis Viticilla, self-clinging Virginia creeper, large roots, several trails, 2/6 each. Clematis vitalba (Traveller's Joy), rapid grower, large roots, 2/- each. Calystegia, double pink, Morning Glory, rapid climber, 3 roots, 1/6. Tropaeolum speciosum, scarlet, 2, 1/6; Aplos tuberosus rooted Wistaria (not sinensis), 2, 1/4. Paeonie Flower, hardy, blue and white, 2, 1/6. Peas, everlasting, white, red, pink, mixed, large roots, 3, 1/6. Eecromocarpus, trusses orange flowers, 2, 1/4. Sweet Pea plants, new, large flowering, waved, etc., lovely colours, 20, 1/6.

BE READY
FOR THE SPRAYING SEASON.
The 'VILLA' SPRAYER

(Brass Cylinder 17in. long x 4in. diam.)

Patent No. 161730.
The cheapest and most effective sprayer on the market.
Will throw a beautifully fine spray any distance up to 18 feet high.
Will spray the underside of a plant as easily as the top.

THE TRADE SUPPLIED.
To be had ONLY of the Patentee.
POST FREE 30, GERALD ROAD, BOURNEMOUTH. 5/-

NOTE—When the fruit is setting after the blossom has fallen, give apple and fruit trees one or two light sprayings with a teaspoonful of Paris-green (Poison) kept well mixed in 4 gallons of soapy water. Sure death to caterpillars; also prevents fruit becoming maggoty. 4 gallons enough for about 24 trees.

Primulas.—Where an early batch of *P. sinensis* is desired, a pinch of seed may be sown at this time. The old double white *Primula*, which is so useful for making up wreaths, etc., must be propagated by means of cuttings, which may be rooted in a warm case at this time; but the usual method is carefully to trim off a lot of the bottom leaves, and then mound up the stems with a mixture of leaf-soil, sand and sphagnum moss. Fresh roots soon push out into this, when the rooted shoots may be cut off and put into suitable sized pots, standing them in a close case for a few days until they get a hold at the root.

Cinerarias.—Although too early for the main sowing, a pinch of seed of both the star and florists' type may be sown at this time where early batches are required. These plants enjoy cool and moist conditions during all stages of their cultivation.

Humea elegans.—Where this beautiful and graceful plant is grown it should now be ready for transferring into its flowering pots, which for well grown specimens should be 6ins. or 7ins. in size; and it is usually at this stage that trouble commences, for this plant is by no means easy to grow well. In my experience it usually gives little trouble in its younger stages if it is grown quite cool and carefully watered, whereas in their final stages they require very careful handling, especially as regards watering. They are very impatient of fumigation, and a sharp look-out should be kept for green fly, which is best removed with a soft brush as soon as it appears. I do not know whether it is generally known that some few individuals suffer from a rash or eczema when banding this plant.

Pelargoniums of the Zonal type rooted last autumn and intended for summer flowering in the conservatory should now be ready for their flowering pots, which may be the 6in. or 7in. size. The plants should be potted fairly firm, and afterwards stood in a position where they can get plenty of light and air. Plants intended for autumn and winter flowering may still be propagated, while earlier rooted batches should be potted on as they require it. When in their flowering pots they should be stood outdoors in a sunny position during the summer months. In the immediate neighbourhood of London it is useless to grow these plants for winter flowering, as one night's fog will ruin the lot.

Royal Botanic Gardens, Kew. J. COURTS.

THE LITTLE GARDEN

Its Value and its Possibilities.

TO a thirsty man a few cups of water are better than an ocean which he can swim in but cannot drink. The widespread love of flowers—would that it were universal and more intense!—is better satisfied by the purity and freshness of a few choice blooms than by an ocean of extensive planting. The former meet a necessity; the latter provides for enjoyment. Yet the ocean has its value. Without it the winds which travel to the four corners of the earth would everywhere pass over a desert. The winds of the gardening world blow over the ocean of extensive culture and gather up its essence, bearing it to distant regions to feed the springs which bring refreshment and beauty to many an otherwise barren spot.

These springs are the little gardens. Though measured in rods they are in no way to be despised in comparison with those which are measured in acres. Nature is infinite, and size is nothing in her presence. The more one is in sympathy with the spirit of Nature, which is the spirit of true gardening, the more evident becomes the potential value of the little garden.

It is a matter of common observation that the greatest specialists among us are the greatest enthusiasts. The treasures which gardening holds are scattered widely, but also buried deeply so that the pearl diver who confines his attention to one spot may easily reap as rich a reward as the explorer who sails round the world in search of variety.

A garden makes its strongest appeal when spring flowers are first coming into evidence. This is partly because flowers are scarce at this time so that the few which do appear stir a deeper interest than their actual numbers would seem to merit. The attention they draw is concentrated and, therefore, intense, and is assisted by the more cheerless winter background against which they appear.

Not alone by winter, however, is a dull background provided. One has only to notice the condition of thousands of the enclosures attached to the everyday dwellings owned or tenanted by "the men in the street" to realise what neglected possibilities lie strewn on every hand. How different might our towns and cities be if only the romance dormant in a patch of soil were appreciated by every lucky owner of a "back yard."

We pride ourselves on being the greatest gardening nation in the world, but there is still room for us to prove that we can be great in little things. It is a reflection on the popularity of the pastime that the term "back yard" should have a derogatory meaning.

There lies a little patch of earth, neglected, downtrodden and hard as the heart of the owner, who sees in it no possible source of intellectual refreshment. Wonderful in its history and composition, richly stored with material which might be built into a living structure worthy of the admiration of a man, teeming with living workers and holding deeper secrets than the wisest among us have yet fathomed, it remains brown and bare beneath the oft-passing footsteps. Yet leave it entirely to Nature for a time and see what happens. Its life-supporting powers find expression and weeds appear. Where weeds can flourish fairer plants can grow.

No serious readers of this paper are likely to miss all the possibilities of the little garden, but it is doubtless in the power of many to influence others who do. If ignorance is the cause there is plenty of information which can be distributed freely with benefit to both giver and receiver.

If interest is lacking it can be stimulated by the healthy infectious enthusiasm of those who know the value of a garden, however small. Various forces are working to forward the movement, but personal influence is the most effective. Individually it may not appear much, but one of Nature's greatest lessons is the importance of little things—be they vitamins or eelworms!

The year 1922 is going to be a great year for horticulture. It will be a great year for the country, too, if it witnesses a wider appreciation of the possibilities of "The Little Garden."

A. E. SIMS.

arranged sparingly in glasses so that each flower stalk is seen, or more thickly massed in bowls, with a plentiful supply of its own foliage, this hardy annual is, no doubt, a super-flower for cut work. To lovers of blue flowers the Cornflower is to be recommended as affording good cutting material, while anyone seeking a mauve tint should grow a batch of the tall *Ageratum mexicanum*. Bright shades of scarlet, carmine, pink and rose are well represented by such favourites as *Clarkia*, *Godetia*, *Larkspur* and *Shirley Poppy*. True the last named is rather ephemeral in character, but if gathered in the bud stage makes a dainty change. Extremely useful for filling large glasses are gatherings of *Cosmea* and *Lavatera* or *Mallow*, both of which genera throw their flowers well out as long sprays or individual stems. The *Sweet Sultan* keeps fresh a long time in water, so is to be prized for vase work, also *Viscaria* and *Zinnias* last well and are fresh and bright.

One of the oldest favourites among annuals for cutting is *Mignonette*, a bowl of which is at all times greatly appreciated because of its perfume. Another old-time plant that offers a good choice for small glass work is the *Carnation*. The annual type is here alluded to, which blooms in six months to eight months from sowing. These flowers, single and double, arrange nicely in glasses for the dining table. *Salpiglossis* is also valuable for cut flower, the rich shades of its funnel-shaped blooms being attractive. Two other plants very serviceable for cutting are *Antirrhinums* and *Scabious*. Neither of these are strictly annuals in the eyes of the authorities but, flowering as they do from mid-summer onwards, the same season as sown, both families are, ninety-nine times out of a hundred grown as annuals. The *Antirrhinums* should be sparsely arranged in large bowls, their superb colours being then most telling, while the single heads of *Scabious* are best used in glasses. Lastly we have the annual *Chrysanthemums* and for late work, *Asters*, particularly single varieties of the latter, than which I question if there is anything finer among annuals for decorative beauty either in the garden or for cut work. Many of the *Asters* resemble Japanese *Chrysanthemums* in form of flower and habit of growth, while their range of colour is not much less than such; likewise they last a long time in water.

It may not be altogether out of place to add that, where the demand for cut flowers is heavy, it will be found a good plan to allocate a bed or border, proportionate with the needs, for the purpose of growing such and so avoid having to deplete those parts of the garden it has been the desire and aim to keep gay.

Amphill Park Gardens.

C. T.

ANNUALS for CUTTING

MANY and diverse are the uses to which annuals can be put, but not all are equally suitable for decoration as cut flowers, a requirement, less or great, in most gardens at some period or other. Some flowers are too stumpy of growth, others will not stand in water sufficiently well to make their cutting worth while, a peculiar shade of colour may rule out another as inappropriate, while others, again, may have to possess fragrance if used in a certain room or on a favourite table, or be barred. This latter stipulation is rare, fortunately, for the possession of the inherent virtue of sweetness is rather limited among annuals, and but few could pass the fragrance test were it common.

Were a vote taken on the subject of these notes, the *Sweet Pea* would, perhaps, be an easy first, so world-wide are its devotees; and whether

Rhododendron Cunningham's Sulphur.—A fortune awaits the raiser of a large-leaved evergreen *Rhododendron* with rich yellow blossoms, the colour, for instance, of *Azalea Anthony Koster*. *Rhododendron* hybridists have made crosses and raised seedlings beyond number in the endeavour to obtain a good yellow flower. *Cunningham's Sulphur* is generally acknowledged to be one of the best hybrids in this direction. It was raised in the Comely Bank Nurseries of Messrs. Cunningham and Fraser, Edinburgh, about 1894, the parents being *R. caucasicum* and *R. arboreum album*. At least, from the point of view of colour, a number of plants of this variety in several places at Kew are one of the most notable *Rhododendrons* in flower during their season. *Sulphur yellow*, perhaps, best describes the colour, a particularly dainty or delicate shade, much admired by visitors. From quite a small size young plants, grafted on *R. ponticum*, flower with more than usual freedom. While healthy and robust in growth, this hybrid

does not possess the vigour of such varieties as Pink Pearl or Lord Palmerston, hence it is very useful as a bedding variety.

Britain's Earliest Roads.—A small but precisely illustrated book* by Mr. Alfred Watkins puts an entirely new complexion on the evolution of trackways or, as we should now say, roadways in Britain. If what he postulates proves true, and it certainly bears the imprint of truth, the Romans must have been adaptors rather than makers of roadways. This is a book that no one with any archaeological or historical inclinations can afford to miss, while it should make a wide appeal to all lovers of the open countryside.

Two Useful "Annuals."—“The Sweet Pea Annual”‡ and “The Carnation Year-Book”§ have just come to hand. Both are full of interest. In the former perhaps the most useful part is the classification of Sweet Peas. Two exceptionally interesting articles are “The History of the National Sweet Pea Society” and “The Early History of the Sweet Pea.” “The Carnation Year-Book” (the official organ of the British Carnation Society) contains the classification of Carnations and Pinks which should prove a great help to Carnation growers. Those interested in Perpetual Carnations and Sweet Peas should be in possession of both these little books.

ANSWERS TO CORRESPONDENTS

TREES AND SHRUBS

REPLANTING FOREST OR WOODLAND (S. M. L., Hants).—We have seen a mature wood of Spruce, and another of Pine (*Pinus sylvestris*), cut down and replanted with the respective kind of trees. The stumps were uprooted in the first case at great expense, but not in the case of Pine or Scotch Fir. The young trees grew satisfactorily, simply by clearing them of rank vegetation once in the course of the summer till the trees got above it. No doubt what our correspondent calls Fir is the Scotch Fir, and there is no reason why he should not plant the same kind of tree again. Many Pine woods were recently cut down in Surrey, and the stumps were not removed. In many cases the ground will soon get covered with seedlings, self sown from the old trees. The Scotch Fir withstands wind, even in the neighbourhood of the sea. It might be worth while planting Beech among the Firs as nurse trees, to be cut out when crowding commences. We are aware that other kinds of trees might follow Fir in Austria and Germany, but we would not recommend Ash near the sea. Beech, Sycamore and Elm would be better, if only as nurse trees.

LARCH AS A SCREEN (G. A. S., Bucks).—A screen of Larch trees will not be a very dense one, nor is it a tree that many would think of planting if the situation were exposed—our correspondent's locality is not particularly exposed and being distant from the sea would not suffer from sea breezes. We would give preference to the common Larch (*Larix europaea*), though a tree of the Japanese Larch (*L. leptolepis*) could be planted at intervals in the row by way of experiment on account of its distinctness. The common Larch is one of the very best timber trees where it succeeds, but is liable to Larch disease, especially in wet situations. It is a good tree for planting under forest conditions on hillsides. The Japanese Larch has longer leaves longer and stouter branches. It has not been long enough in this country to have its capabilities tested as a timber tree, but has every appearance of being a lower tree in this country than the common one. The common Larch grows quite well and freely in a gravelly soil; and the other will for a time at least. Plant them no deeper than they were in the nursery, and this can be seen by the soil-mark at the base of the stem. The common Larch will grow 20ft. to 25ft. from seed in ten years in the counties around London. In fifty years it will grow 80ft. high where it thrives; in a single row of trees it would not progress so fast. The Japanese Larch grows more slowly than this. The roots do not travel so far as those of Ash, Elm and Beech by a long way; they will, however

extract the moisture for some feet. The shade produce is very small. As Larches come into leaf and bloom before the Beech, we would prefer to plant them in February or March, because it is very exhaustive to them if the young leaves get killed owing to drought before the roots get hold of the soil.

MISCELLANEOUS.

WHERE TO OBTAIN WATTLED HURDLES (T. S. T., Somerset).—The hurdles may be obtained from Mr. Dowland, Highcliffe, Christchurch, Hants. Mr. Dowland is an expert in making these hurdles.

THE SOYA BEAN (P. R.).—The Soya Bean (*Glycine Soja*) and the Locust (*Ceratonia Siliqua*) both belong to Leguminosae, the former being an annual extensively cultivated for the seeds in Manchuria, China and Japan while the latter, a tree of 20ft. to 25ft., native of the Mediterranean region, is valued for the pods, which contain a saccharine substance and are valued more particularly as a food for stock. The seeds contain a gum said to be used by calico printers as a thickening agent.

THE DESTRUCTION OF WHITE FLY.—T. F., Bedale.—A little booklet, entitled “Tomato Cultivation Under Glass and Out-of-Doors” (published at this office, price 11d., post free), deals fully with this important subject. Hydrocyanic acid, which is the only effective agent for the destruction of this pest, is a very dangerous poison and should never be used until the necessary details are thoroughly mastered.

IRISH POTATO GROWERS (E. A. L., Henley-on-Thames).—Firms who grow Potatoes in Ireland are Messrs. Alex. Dickson and Sons, Newtownards, County Down, Ireland (or 61, Dawson Street, Dublin); Messrs. Hogg and Robertson, Limited, Nurserymen and Seedsmen, Dublin; and Manager, Lisadel Sligo, Ireland. There were other growers of Potatoes in Ireland, but whether the firms now exist or not we cannot say. Two well known growers and specialists are Mr. William E. Sands, Hillsborough, County Down, Ireland; and Mr. J. F. Williamson, Seed Potato Specialist, Mallow, Cork.

NAMES OF PLANTS.—B. E. S., Lockerbie.—Cornus Mas (the Cornelian Cherry).

NAMES OF FRUIT.—C. S., Salisbury.—Apples: 1. Probably High Canons; 2. Beauty of Stoke; 3. Hornead Pearmain; 4. Winter Quarrenden; 5, too decayed for identification.

No. 2630.—VOL. LXXXVI.]

[APRIL 15, 1922.]

THE DAFFODIL in INFORMAL PLANTING

At this season the would-be planter can study at first hand the arrangement of the Daffodil and enter in his note-book, under September, his impressions of the best varieties and their most effective arrangement.

IT would not be quite accurate to say that of all plants the Daffodil gives, when naturalised, the best effect, but those most competent to judge would probably consider some of the artificially reared *Narcissi* among the most suitable of plants of garden origin for naturalising, or producing natural effect.

The old Lent Lily (*Narcissus Pseudo-narcissus*) of our damp meadows has real beauty, but despite the glamour which always attaches to a wildling, it is too short of stalk, too stolid and compact, to give the graceful effect produced by adequate masses of Emperor, Sir Watkin, *Barrii consociatus*, or the May-flowering Pheasant's Eye.

The planting of woodland with Daffodils was undertaken by a few artistic minds a generation ago, but it is only of late that it has really become fashionable. Still, fashionable or unfashionable, it is an eminently desirable practice and one which will bear indefinite extension. English woodland, or some of it, has wonderful natural displays of mass

DAFFODILS IN THE BIRCH GROVE AT WARLEY PLACE.

planting, as witness the Wood Anemones and the Bluebells, or, perhaps, more beautiful than all, the Primroses which, like the Daffodils in general colouring, transfigure the woodlands of the Weald and of many other parts of England. Yet none of these can out rival the beauty of bold plantings of Daffodils, especially when the latter are planted carefully and so arranged as to form a perfectly proportioned picture.

A woodland crowded with Primroses never becomes a mere stretch of colour—the undergrowth, however scanty, sees to that—and though it is possible to strike a veritable sea of Bluebells, yet some divergence of growth and the light and shade among the boles suffice to redeem the picture from monotony.

With the Daffodil the case is different. Just because it has in itself more development of form—more individuality it may be—than the Bluebell, its effect is more dependent upon good arrangement. Little clumps, even of one variety, dotted over woodland, orchard or pasture give a very unsatisfactory "spotty" effect; small groups of assorted varieties are an offence. When we come to the opposite extreme quite solid planting of large areas with one variety is very little more satisfactory. The natural grace of the flowers is no longer apparent and we get an effect similar to that to be seen at a nursery where bulbs are largely grown for cut flower.

The plantings which the pictures illustrating these notes depict show that restraint which is the surest sign of excellent taste. The picture of the Heath garden at Gravetye is introduced to show what is still an unusual, but withal a very natural and suitable combination. It may be permissible to point out that other bulbs besides Daffodils thrive well and are happily placed in association with Heaths, notably the Dog's Tooth Violets (*Erythronium*) and the Snakesheads (*Fritillaria Meleagris* and related species).

Not every garden-lover has woodland or orchard in which to display his Daffodils, but after all, a little space well treated will afford almost, if not quite, as much pleasure as a large one if only it be perfect of its kind. The upper picture on this page sufficiently well illustrates the point. Not only is the grouping admirable both in spacing and in actual size for the space at disposal, but the varieties, with their exceptional intrinsic beauty and refined but exquisite colouring, are ideal for the purpose. One feels that some would have been too large, too stiff and formal for these quiet positions, while other kinds would be quite out of the question.

The natural arrangement of Daffodils or other bulbous plants is not difficult if due care and forethought be brought to bear. It is first of all necessary to stake out the proposed groupings and to visualise the effect when the plants are in flower. Once the whole thing is staked out it should not be difficult so to modify the arrangement as to get the effect desired, but it is very necessary when planting not too slavishly to follow the curves laid out. It is wise to "sow" the bulbs in handfuls much as one would broadcast seeds, keeping, of course, roughly to the lines marked out. The bulbs are then planted where they fall either with a special bulb planter or by stripping off the top spit and replacing it with a spade. In the latter case it will be more convenient to "sow" the bulbs after the soil is removed. They should, in any case, be buried to about twice the depth of the bulb.

This question of the arrangement of bulbs will be more fully dealt with at the usual planting season, but it may be well to point out that where overcrowded bulbs need thinning, there is often no occasion to wait until autumn to replant, which involves considerable storage and trouble. If the land to be planted is not already under grass the ripe bulbs may be recommitted to Mother Earth at the earliest opportunity, not only without ill effects, but with great advantage, though if the presence of eelworm is suspected the hot-water treatment, which has proved so successful and of which we hope to publish further particulars very shortly, should first be put into operation. On no account, however, should the bulbs be lifted until the foliage has entirely ripened off, nor if they are growing in turf should this be mown until this

A CHARMING DAFFODIL WALK.

"A HOST OF GOLDEN DAFFODILS."

ripening is complete. The necessity for allowing the foliage to ripen naturally is an unsurmountable obstacle to the growth of Narcissi in closely mown greensward. One not seldom sees them introduced into what should be a closely shaven sward, but the effect when the grass has sprung up between them is very objectionable, while the fine grasses inevitably die out and the verdure becomes coarse.

Daffodil planting in the wild garden is a comparatively inexpensive hobby if the older, but quite effective, kinds are purchased. There is, once the planting is done, practically no expense of upkeep unless it be that, after a term of years, it will be necessary to lift and replant the bulbs. When this becomes desirable, however, the bulbs will largely have increased and a surplus will be on hand for further plantings.

All Daffodils prefer a rather moist soil, but some sorts are much less exacting in this respect than others. The Lent Lily grows wild in rough, more or less swampy, ground and similar conditions suit the magnificent May-flowering Pheasant's Eye (*N. Poeticus*) and, to a lesser extent, its useful early-flowering varieties, *ornatus*, *Burbidgei* and *poetarum*. Probably the new *Poeticus* varieties, now so numerous, will succeed well in turf, but those mentioned are all beautiful; they are procurable by the thousand and they are reasonable in price.

Of Trumpet Daffodils the following all succeed in turf. They are plentiful, cheap and provide much diversity of form and colour. The Tenby Daffodil, *N. princeps*, lacks the size and substance of others to be mentioned, but it is early and free and very effective when massed; colour sulphur yellow. Golden Spur is a rich golden yellow, also early to flower and, though not large, of excellent form. Emperor is at present the largest shapely rich yellow Daffodil available for naturalising, though it will probably eventually give place to the giant King Alfred even for this purpose. Empress is at present the best bicolor (white perianth, golden trumpet) variety for mass planting. The beautiful creamy-white *Mme. de Graaf* is being planted to an ever increasing extent. The species *Moschatus albus* has a grace of form exceeding even *Mme. de Graaf*, but it is not, unfortunately, too easy to establish. A moist soil and a thin pasture in shade without drip would seem to suit it best, but it is apparently a capricious plant.

Of other Narcissi only two are of real importance. These are *Barrii conspicuus* and *Sir Watkin*. Both represent crosses between the Trumpet Daffodil and the short-cupped Narcissi; *Barrii conspicuus* has the short trumpet broadly edged with orange of the Narcissus combined with the substantial perianth of the Daffodil. It is accommodating, but shows to greater advantage

and carrying its flowers well aloft, it should not be planted too closely.

Beyond these two there are a host of rapidly increasing Narcissi, such as the old *Stella*, which look well enough in quantity but lack at once the finish and colouring of *Barrii* or *Sir Watkin*. Some of them are very cheap and are often, for that reason, employed in extensive plantings

DAFFODILS IN THE HEATH GARDEN AT GRAVETYE.

in a cool, rather moist corner. *Sir Watkin*, which is, if possible, easier to do than the other, has the same substantial perianth of sulphur yellow combined with a rather more deeply coloured cup about midway in size between the short-cupped forms and those with long trumpets. A vigorous grower

Quite apart from these again are the beautiful Leedsii forms which succeed wonderfully in turf but which, like *Mme. de Graaf*, are most effective when close at hand. Of these *Mrs. Langtry* and *Duchess of Westminster* are sufficiently alike to be used alternatively or even mixed together!

SPRING BEDDING

It is not too soon to decide upon next year's display. Put it in hand now.

A HAPPY COMBINATION IN THE SPRING GARDEN—FORGET-ME-NOTS AND TULIPS.

IT must be admitted that in the average garden Wallflowers are not grown well. A good single Wallflower, before it runs to flower, should be almost as level topped as a table and should be close upon a foot across. It is easy to make a satisfactory ever-green bed for the winter with such specimens, and when their spikes expand in spring, their massed colouring can hardly be surpassed.

The Wallflower does not require indeed it resents an over-rich soil, but it should be started early and have attention when required throughout its period of growth. The actual sowing may be carried out at this season. It should certainly be undertaken before the end of the month. Very shallow drills drawn a foot apart in nice crumbly soil in the open garden will answer, but they must be protected by cotton from ravages of birds. If lights are available, a rough "box" a few inches high and the size of the lights which are to be employed will enable the soil to be kept evenly moist until the seedlings appear.

The seed should, in any case, be sown thinly, and the resultant seedlings when about 2ins. high should be thoroughly soaked, then lifted and pricked out quinnix fashion in nursery quarters about a foot apart each way.

The plantlets, as lifted, should first be taken to

the potting shed, and there they should be "topped and tailed"; that is, the tap-roots should be shortened to ensure a maximum of fibrous roots, and the extreme growing points should be pinched out in order to produce an equally bushy, well branched head. The planting should be especially firm. The soil between the rows should be stirred as necessary to assist aeration and to keep down weeds. Once the plants are established, if the bed is kept stirred there is little likelihood, on most soils, even in exceptional seasons, of the plants suffering from drought.

The Wallflower is an accommodating plant, but it is very desirable to get it into its permanent quarters while the ground is still warm in autumn. The beautiful double varieties should be given the same treatment as the single ones. For them a long season of growth is especially important, and if success is to be achieved, the soil in which they are to be grown should not be over-poor. It is perhaps well to make clear that good single Wallflowers cannot be grown in *over*-poor soil. Double Wallflowers are far less hardy than single ones and should not be used for important beds except in the South.

Polyanthuses, it has often been pointed out in these columns, are most successful for spring display, whether in beds or wild garden, when

treated as biennials. The seed, if not already sown, should be got in without delay, either in boxes or, preferably, in a bed of nice loamy soil in a frame with a north aspect. Progress is at first much slower than with the Wallflowers—indeed, germination is apt to be uncertain with old seed—but once they have braided and "got away" progress is rapid, and it is most important to prick them out—7ins. or 8ins. apart each way—before they become overcrowded. The nursery bed selected should be at least partially shaded from the heat of the sun and should be within easy access of water, as the Polyanthus abhors drought.

The middle of May will be soon enough to sow seed of Forget-me-nots. An excellent method of raising these is to lay in the old plants, as removed from the beds, thickly together in rows about 2ft. apart, reducing the intervening ground to a fine tilth and keeping it really wet by watering with a fine hose. The seedlings, which will come in multitudes between the rows, should, as soon as large enough to handle, be pricked out in fairly good soil 5ins. apart.

Of that excellent bedder *Silene pendula*, with rose, white or carmine-red flowers, it is only necessary to point out that sown now it will flower this autumn. August is soon enough to sow for spring display.

THE HIMALAYAN POPPYWORTS

TO speak of those glorious plants, the various Asiatic species of *Meconopsis*, as biennial is scarcely correct, for while in the majority of cases they die after flowering and setting seeds, they often grow for three years before they reach the flowering stage. It is a matter of the greatest uncertainty—some seedlings grow away and flower as a matter of course in their second summer, while others continue to grow and throw up leaves for two or three years before doing so. In the latter case, they continue to accumulate strength and vigour all the while, and when they do at last blossom forth, the spikes and flowers are all the larger and finer.

Being biennial we must raise our seedlings annually either as soon as the seed is ripe or sowing in early spring in a cold frame. Whenever they are sown, I strongly recommend the sowing in seed pans in a cold frame, for they are too precious to expose to the uncertainties of wind and storm. This remark does not apply to *M. cambrica* and its varieties, for this is so astonishingly fertile that seedlings spring up literally in thousands all over the place; indeed, I should hesitate to introduce it anywhere except in the wild garden or the rougher places, for once it obtains a foothold in a rock garden where there are choice plants it becomes a veritable weed. No such fear need be entertained with the double variety of this, a really choice thing that reproduces itself all too sparingly.

M. aculeata is a truly superb flower, introduced a few years ago from the Himalayas. It forms a rosette of bright green leaves clothed with fine silvery hairs, from the centre of which pushes up a loose terminal panicle of the palest blue or mauve flowers with a cluster of golden yellow stamens at the centre. These flowers are wonderful in the early morning while the dew is still on the grass and they have just freed themselves from the sheaths that encased them. The petals still retain much of the wonderful crinkle that results from the close packing into the buds and yet reveal the wonderful mass of anthers at the centre. These are as yet damp and clogged together in masses, but as the atmosphere dries they separate and the pollen becomes dehiscent, as the botanist says, showering down on to the lower petals at the slightest touch. It is a long-lived flower too, as the buds continue to open in succession one after another for some weeks. *M. integrifolia* is a gorgeous Chinese species, 2ft. to 3ft. high and freely reproduced from seed. The foliage is a beautiful woolly green, while the flowers, which are drooping, are pale primrose yellow with stamens of the same colour. There are two distinct forms of this under the same name, that introduced first bearing several flowers on a separate pedicel branching from the main stem. The later species produces a number of stems from each root, each of which bears a single flower. *M. nepalensis* is a very rare plant, difficult to

obtain and to keep. It has branching stems and brick red flowers, but I must confess that I have never seen this. *M. paniculata* is often confused with the above and a very fine plant it is, the foliage being thickly covered with silky hairs and the branched stems covered by drooping golden flowers.

M. punicea is a very remarkable species, the drooping flowers of which should be turned upwards to appreciate their full beauty.

M. racemosa is very similar to *aculeata*, but much bluer and quite as attractive, when first expanded the crimping of the silky petals being very noticeable.

M. simplicifolia is very dwarf; in fact, quite the dwarfiest, not exceeding 1ft. in height and more often about 6ins. The flowers, which are blue, are solitary, opening in July.

M. Wallichii, the Satin Poppywort, is notable for its beautiful foliage, which is much divided and smothered with silky hairs. The strong, tall, branching stems bear numbers of wonderful satiny blue flowers, the whole plant rising to 4ft. or 5ft. in height. After a shower or heavy dew the prettily cut foliage and golden hairs form a wonderful sight, as these hold tiny beads of moisture-like glistening pearls. A soil composed of fine peat, leaf-mould and sand is the ideal medium in which to plant, for they have a marked preference for a soil that is light and yet retains moisture.

THAT GOLDEN FOLIAGED TREASURE, *MECONOPSIS WALLICHI*.

PALE BLUE PLATTERS AND DEEPLY LOBED FOLIAGE OF *M. ACULEATA*.

Partial shade is also desirable for all varieties, so that evaporation is not too rapid. Where growing in full sunlight they must be copiously supplied with moisture, and even then do not, as a rule, attain the full stature that they will in partial shade.

The plants are quite dormant all through the winter, though the very woolly leaves persist and must be protected from excessive wet by placing a sheet of glass over them, raised a few inches

will provide plenty of excellent cuttings quite early in autumn, and these, rooting quickly in the warm soil, will next April be admirable plants just fit for planting out.

The large-flowered Pentstemon seems of late years to have suffered something of an eclipse, its merits having been largely obscured by the many excellent strains of Snapdragons on the one hand and by the small-flowered Pentstemons of the Gem class on the other.

saved from these. Pentstemon seed is as well sown as soon as ripe, but it keeps moderately well and may be sown under glass early in the year or in a cold frame at this season. Seed may be procured in the first instance, but it is advisable, in that case, to procure it from a firm that specialises in these plants.

Tastes naturally differ, but the writer must acknowledge a partiality to the still rather uncommon pale mauve shades, some of them so pale that the expanded flowers are pure white. The pale pink and soft rose shades are, however, very beautiful; the deep maroon sorts, some with immense bells, give dignity and weight to the border. The so-called scarlet and crimson varieties, which are undoubtedly the ones most commonly used, need careful arrangement.

The red and rose shades of the Pentstemon have that admixture of blue which characterises the flowers of such plants as the Mallow and its relatives, the Lavateras and the Sidalceas, the Japanese Anemones and the Cosmos. This type of colouring is apt to clash badly with the clearer, cleaner shades with yellow in their composition which are yielded by many varieties of such plants as the Snapdragon, the Phlox, the Gladiolus and the Lily.

Pentstemon Newbury Gem and, to a somewhat smaller extent, the others of the Gem class will stand an average winter outdoors in the South-West and more favoured parts of the Midlands of England; but, like the Wallflower, it is most useful and effective when renewed each year in the ordinary way. Rightly or wrongly, but the writer thinks wrongly, it has of late years been largely superseded by the larger-flowered, looser-habited Southgate Gem, which is hardly so satisfactory in colouring.

The great justification for the Pentstemon's existence lies in its value for replacing in the herbaceous border, plants such as the Oriental Poppy, the Leopard's Bane or the Aquilegia, which flower early and which would, if not interplanted, produce unsightly gaps. This certainly is where the more robust Gem class prove their worth, since they may be kept in pots even into June and will then quickly over-get the check of removal.

Of large-flowered varieties there are a multitude, but the especially recommendable: Emile Rodigas, scarlet-crimson; Rosamund, soft rose; Spitzbergen, palest mauve, opening white; and President Carnot, maroon.

THE VERY DISTINCT SULPHUR-YELLOW MECONOPSIS INTEGRIFOLIA.

so that air can circulate, but the glass must be removed immediately new growth starts in spring. Precautions must be taken against slugs, which are partial to Asiatic species at all stages of their growth.

H. W. CANNING-WRIGHT.

THE USEFUL PENTSTEMON

THE season has once more arrived when Pentstemons may be planted out in their permanent situations, but before lifting the rooted cuttings in earnest, it is wise first to try one or two to assure oneself that they are thoroughly well rooted. If the cuttings were, for any reason, put in rather late, or if the frame in which they have rooted is not a particularly sunny one, they may be backward, for cuttings of this plant take a considerable time to form roots. If they are, even now, not well rooted it is better to leave them another week or so, as they should make rapid progress at this season. Spring winds are notoriously drying, and one cannot expect inadequately rooted plantlets to withstand them. It is none the less most advantageous to get the plants established early, so many growers, about February remove the cuttings from the cold frames in which they have wintered and struck and, potting them up singly in 3in. pots, bring them forward first in a little heat and, after they are established, in a cool greenhouse.

This method, however, makes work and also necessitates the occupation of a deal of valuable space which may easily be avoided if plants are reserved every year at this season for stock and not allowed to bloom. Such plants, if well grown,

Snapdragons may, we know, be readily raised from seed, and the small-flowered Pentstemons throw cuttings much more freely than do the large-flowered ones. On the other hand, the small-flowered sorts, though invaluable, are mass plants, like the Catmints, owing their value to the associated colouring of the group rather than to any particular form or grace inherent in their flower or habit of growth, while the best of the large-flowered kinds may hold up their individual spikes unshamed even in comparison with the Gladiolus or the Phlox.

Named varieties of much excellence may be obtained from the specialists, and seed may be

“MAGGOTY APPLES”

Their cause and prevention.

EVERYONE who grows or uses fruit is familiar with so-called “maggoty Apples.” These occur now and again in even the best regulated plantations, while in old and neglected orchards and gardens it is sometimes difficult to find a sound one. In spite of this, but few people know much about the cause of the infestation, or the origin of the “maggots” they find in their fruit. Moreover, there seems much confusion among gardeners between the two insects responsible for this damage, viz., the Apple sawfly and the codling moth.

The Apple sawfly is the least known of the two, and the damage done by its larva is often attributed to the codling moth, but is really of quite a different nature.

The sawfly is a small insect, about a quarter of an inch long and five-eighths of an inch across the

expanded wings. The general colour of the upper surface of the body is black, and orange underneath. The females may be found resting on the Apple blossom in bright sunlight, during which they deposit their eggs, usually during the morning, placing them on the ovary below the calyx.

The eggs, which are laid singly, hatch soon after the falling of the blossom, and the newly

THE APPLE SAWFLY.
Hoplocampa testudinea (· 2)

APPLE FRUITLETS ATTACKED BY THE APPLE SAWFLY.
(Slightly reduced).

hatched larva commences to attack the tiny fruitlet on which it finds itself.

For a day or two the young larvæ feed on the outside of the fruitlets, which they occasionally fail to enter through working along the side, and then their work is usually manifest in the form of an elongated brown scar on the full sized Apple.

They generally enter the fruitlet in a day or two, however, passing through the side or base, but *not* through the calyx, as is the case with the larvæ of the codling moth. They make their way to the core, which they entirely devour, together with the greater part of the centre of the fruit. They feed voraciously and rapidly increase in size, so that the resources of the first fruitlet are soon exhausted. Consequently they leave it and enter another, and each larva probably destroys several fruitlets in this way.

The attacked Apples may be detected when very small, by having a little round hole at the side, from which a wet brown mass is exuding. Later on, the hole becomes larger and is much more noticeable, but it is important to look out for the attack in its early stages.

If one of these fruitlets be cut open, the centre will be found more or less hollowed out, and the cavity filled with a wet, sticky mass of brown excrement, which also exudes from the entrance hole. The larva, if still present, will be a fat cream-coloured caterpillar, with twenty legs, and is thus easily distinguished from the larva of the codling moth, as shown later on.

The writer has never found a sawfly larva in an Apple larger than about $\frac{1}{16}$ in. in diameter, and it is probable that most of them are full grown by that time, as under normal conditions there is usually only one brood during the year.

The damaged fruitlets may occasionally remain on the tree, where, if undisturbed, they will hang in a mummified form all winter; but normally they fall from the tree in the later stages of the attack, the larger fruitlets still containing the larvæ, which soon leave them and pupate in the soil. Before pupation they shrink considerably and spin a parchment-like oval cocoon of a dark brown colour and about a quarter of an inch in length. Within these cocoons they undergo their transformations and emerge as sawflies the following spring.

This insect is not common everywhere, but is usually abundant where it occurs at all. It is a

pest which seems to be on the increase, at any rate in the district from which I write (North Hertfordshire), and it is therefore important that measures be taken this spring to check it.

Being an internal feeder, but little can be done when once the fruit is attacked. If discovered in the early stages, some good may be done by hand-picking the attacked fruitlets and either burning, or burying them deeply, or giving them to pigs. This would require too much labour to be profitable in large orchards, but is certainly worth doing in gardens where only a comparatively few trees are present, and the fruit will benefit by the thinning. If much of the fruit should fall, it must be gathered up as soon as possible and effectively disposed of, and if a soil fumigant were forked into the soil around the affected trees it would no doubt destroy many of the larvæ before they had a chance to pupate.

These measures cannot, of course, be regarded as remedies, and are merely the necessary precautions to prevent the spreading of the attack and its recurrence next season.

The best preventive measure is to spray with lead arsenate as soon as the blossom has fallen, so that the fruitlets get covered with the poison before the sawfly larvæ hatch. Then, when the larva emerges from its eggshell, the first bite it takes is likely to be its last.

If, in spite of this spraying, some larvæ are found to be present, the trees should be sprayed again

APPLE FRUITLETS OPENED TO SHOW SAWFLY LARVÆ INSIDE.
(Slightly reduced).

a week or two later, when many would be poisoned as they change their quarters and start on a fresh fruitlet. It is important to use a lead arsenate that has good adhesive properties.

The "maggots" found in large Apples are invariably the larvæ of the codling moth, an insect which has been known for at least four centuries.

As these two insects are frequently confused, it is well to note the points of difference between their larvæ and methods of feeding.

The Apple sawfly larva is white or cream coloured, stout, and has twenty legs. The codling moth larva is usually of a pinkish tint, comparatively thin, smaller than the sawfly larva, and has only sixteen legs. While the sawfly larva usually enters the fruitlet through the side, the codling larva always enters through the "eye," or calyx, and so leaves no apparent hole after the calyx has closed up. Later on, when the Apple is fairly large, it makes another hole to the side; but this is an exit and not an entrance hole.

The codling larva does not destroy the fruit to anything like the same extent as the sawfly. It feeds more slowly, and whereas the latter makes

a great cavity in the centre of the fruit, the former only makes a few tunnels in and around the core.

The codling moth is about half an inch across the wings, which are greyish in colour, with a large brown blotch at the hind margin of the front wings, which have a beautiful satiny sheen

YOUNG APPLE DAMAGED BY LARVA OF CODLING MOTH.
(Natural size).

when seen in a certain light. The moth appears just about the time the blossom is falling and lays its eggs on the fruitlets. The eggs are a pearly white and glisten like a drop of dew. As soon as the larva is hatched, it makes its way to the calyx, on which it feeds to some extent before actually entering the fruitlet.

When full grown the larvæ leave the fruit and fall to the ground; then make their way either to a tree trunk or a post or fence near by. They crawl some way up the first object they come in contact with, and spin a cocoon in a crevice, in which they hibernate, pupating in the early spring.

The placing of "hay bands" round the tree trunks is a very old custom. The larvæ spin up in these, which are then removed and burnt during the winter, and quantities of larvæ may be destroyed in this way. Loose bands of old sacking are equally effective and easier to apply. A favourite place for the codling larvæ to spin up in is in the bands of felt or sacking used when young trees are tied to stakes.

As in the case of the Apple sawfly, the only chance of poisoning the larva is when it is feeding externally, and it is therefore necessary to spray within a week of the falling of the blossom, so that the arsenate may lodge in the calyx, while the latter is still expanded. If the trees are thoroughly well sprayed at this period, there is little chance of having "maggoty Apples."

RAY PALMER, F.E.S.

THE CODLING MOTH.
Carpocapsa pomonella. ($\times 3$).

THE PROPAGATION OF MINT

MINT is one of the most popular herbs cultivated in gardens, although it is sometimes neglected by the amateur gardener. Many people are content to buy a quantity of Mint, dry it and place it in bags for future use. This is justifiable when the gardener has no facilities for forcing

ROOTED MINT CUTTINGS.

Mint, but there are folk who, even when this herb is in season, use the dried stuff, either because they are unable to procure the succulent green tops or because they consider it too troublesome to be worth growing.

The cultivation is in reality quite simple and, given a fair start, it will not require much attention. There are several species, but the one generally cultivated is the Spear Mint (*Mentha viridis*), which is used in its green state—forced or otherwise—for culinary purposes. The dried leaves are a poor substitute when the new Potatoes arrive.

Increase of stock may readily be effected at the present season. The work may be carried out in two ways, either by division of the clumps or by taking cuttings. Undoubtedly the latter method is preferable. By inserting cuttings at the present time, clean healthy stock will be secured. Division of the clumps is effective, but the growths will not be so vigorous or of the same quality as stock raised from cuttings. These should be taken off an inch or so below ground level with a root or two attached—much as one takes *Viola* cuttings, in fact. They will root freely if dibbled into moist sandy soil, especially if a handlight can be spared to place over them for a few days, giving shade when necessary.

The accompanying illustration shows two rooted cuttings. The cuttings should be inserted in the ground up to C, but a little deeper will not hurt in light soils. The longer cutting should be shortened to A before insertion, to prevent undue strain upon the root action. B shows the rootlets.

Mint thrives best in rich moist soil, but it really is not fastidious. It is, however, advisable to manure light, hungry soils.

Failure with Mint is as a rule attributed to the poorness of the soil, but the most frequent reason is that the gardener in the autumn or winter

when digging the garden covers the Mint over with a few inches of soil, and in consequence the shoots are unable to make their way through. Where a bed of Mint has been in existence for some years a depression in the ground is generally to be found, and the gardener in the interest of neatness levels up his soil.

A bed of Mint will thrive, when established, for several years without attention, but to obtain the best quality it is advisable to propagate every year. Cuttings, or "sets," as they are called, should be put in a foot apart each way. They should then be a solid mass of roots by late autumn. H. G.

Stopping and Potting Large-Flowered Chrysanthemums

This work, to the expert cultivator, is easy enough, but the beginner finds it very perplexing. The brief notes and sketches should make all these matters quite plain to him

THE result of a year's work may depend upon the treatment that the plants receive during the trying time when they are producing buds to cause the first, or natural, break or when they are stopped—the points of the plants pinched off to cause the break just at the time most suitable for certain varieties. I do not intend to deal with particular varieties, as too much space would be required, but with the general treatment of the plants as regards stopping, final potting and staking.

The first break is caused, really, by the formation of a crown bud around which shoots grow; this bud stops the free growth of the single stem and causes a number of side shoots to grow, which, in due course, overcome the bud, the latter shrivelling up. If three blooms are required on a plant, the three shoots immediately below the bud are trained to stakes and the others, still lower down, are rubbed out. This break-bud formation does not occur naturally at the right time for certain varieties, in which case the cultivator must cause a break by stopping the shoot—pinching off the point. Natural breaks occur during the latter part of April, during May and the first half of June mainly. The latest flowering varieties are the ones chiefly to be stopped; a few of the medium sorts need this attention too in order that all may be in bloom at the same time, say the first week in November. The earliest flowering varieties rarely need to be stopped.

If a plant needs stopping remove the point of the stem as shown at *a*; the three side shoots, *b*, *c* and *d*, must, in due course, be taken on and trained to stakes; all other shoots, as shown below, are removed. When the bud forms and causes the natural break, *e*, *f* and *g* respectively, are the new shoots to be trained to stakes; *h* shows the bud which may be removed or left to wither; *i*, *i*, *i* show when the lower side growths must be rubbed out. The next sketch shows the progress of these new shoots. The bud was formed at *j*, and the three shoots *k*, *k*, *k* are making good headway; *l*, *l*, show shoots removed.

THE FINAL POTTING AND STAKING—Old turves, cut long enough for the grass roots to die in them, should form the bulk of the compost. Sweet leaf soil, three-parts decayed, sand or old mortar rubble, a few wood ashes, bonemeal and horse manure fermented, without undue heating and burning, are the other ingredients. Firm potting in clean, dry pots, well crocked, and judicious feeding and top-dressing as required, coupled with careful attention to watering and tying of the stems, should result in a good harvest of high-class blooms. The letter *m* shows the rougher portion of the compost placed on the crocks; *n*, *n*, show how the permanent summer stakes are driven into the new compost and not into the ball of soil and roots. When the work of potting is finished ample space must be left at the top, *o*, to allow of top-dressing being carried out as the large pots fill with roots.

AS REGARDS THE STAKES—If bamboos are used as shown at *b*, very little dressing will be needed; but if ordinary hedge or wood stakes are employed, as shown at *q*, then it will be advisable

to trim off all knots smoothly, else the tying material will be held by the knots *r*, and result in the stem of the plant, *s*, being snapped off. The raffia or tying material does not slip up the knotted stakes as the stems of the plants carry it up. In

HOW TO STOP, POT AND STAKE CHRYSANTHEMUMS.

the case of the smooth bamboo stake there is not this danger. All stakes must be well sharpened to needle points as shown at *l*, and not left with a blunt point as shown at the letter *u*. G. G.

CORRESPONDENCE

A SELECTION OF SHRUBS.

IN reply to a letter from your correspondent, "H. E.," with reference to shrubs and trees suitable for a chalk soil (THE GARDEN, April 8, page 167), the following list may be of some use to him. I have classified it separately in order that he may realise the difference of growth. In a short note, such as this, it is hardly possible to give a detailed description of the individual habits of each plant. Trees: Acacias in variety, Beech in variety, Gleditschia triacanthos, Chestnuts, Norway Maple, Japanese Maples, Sycamore, Mountain Ash, Pyrus Sorbus, Flowering Thorns. Large-growing coniferae: Austrian Pine, Scotch Fir, Spruce Fir, Thuiopsis borealis, Cupressus Lawsoniana and varieties, Silver Fir. Smaller-growing coniferae: The whole of the Juniper family, the more dwarf varieties of Cupressus. Other evergreens: Hollies in variety, Yews in variety, Portugal Laurel, Veronicas of sorts. Olearias, Laurels, Cistus, Laurustinus, Japanese Privet and other varieties of Privet, Daphnes of sorts, Pyracanthas of sorts, the Evergreen Berberis. Of deciduous shrubs a large selection can be used, and the following would, perhaps, be a sufficient mixture to include with the above: Berberis of sorts, Deutzias, Elders, Viburnum of sorts (Guelder Rose), Lilacs, Philadelphus of sorts, Pyrus japonica, Ribes of sorts, Snowberry, Weigelas of sorts and Spiraeas of sorts.—F. GOMER WATERER.

PLANTING AND TRANSPLANTING TIMES.

THE discussion on planting and transplanting (pages 145 and 155) has interested me. I have heard some gardeners say that they could transplant during almost any month of the year. A nurseryman told me some years ago that he has transplanted conifers in July for lack of a more convenient time to do it. Doubtless this could be done just when the trees have made and hardened their season's growth. This also applies to Privets and Euonymus, which make several distinct growths during the year. If these are moved at other times than when leaves and shoots are young and tender they will succeed. Conifers in nurseries are, in normal times, easy to move, because they are transplanted every few years with this object in view. I have assisted to transplant Irish Yews, Abies and Beech 7ft. to 10ft. high in May, and they succeeded, although they had been growing in the same site for many years. The reason why autumn is such a favourable time for transplanting is because trees have made a considerable amount of reserve food, and a large portion of this is carried downwards to extend the root system, as soon as the autumn rains have moistened the ground. The extension of the roots continues for some time after the leaves of deciduous trees have fallen. I have noted this also in Roses, Loganberries and Strawberries. Scabiosa caucasica and its varieties must not be transplanted in autumn, but in spring, and the leading growers are now aware of this fact.—HORTULANUS.

NOTES FROM GLOUCESTERSHIRE.

A FEW notes from this part of the country from one who is quite new to it may be of interest. It is in the heart of the hunting country, Badminton district. I am much struck with the large gardens attached to the cottages, but in no district have I seen them so neglected. It is the A B C of the work that is ignored, so that digging seems left till March; it is a great contrast to the orderliness and love of their gardens of the villagers of the East Coast. The Madonna Lily

flourishes amazingly, the foliage so strong and healthy. In one garden against the house, in a border 7ft. long and under 2ft. wide, they looked almost too crowded to flower, yet they yielded nearly 100 spikes of bloom. Could any reader inform me if other Lilies are likely to do well? We have cold winds from the west; the top-spit is a fertile loam, but clay 12ins. to 18ins. below. Pyrus japonica is a wonderful sight here, full of blossom.—B. P. G.

A PLANT FOR A DAMP OR SHADY POSITION.

THAT very attractive plant, Heloniopsis japonica (syn. Sugerokia), which comes from damp or shady woodlands in Japan, might with advantage be used more freely in our gardens where suitable positions offer. The plant, as the name suggests, is botanically related to Helonias bullata, a liliaceous plant which, under the name of "Stud-flower," is rather better known, although

USEFUL FOR DAMP OR SHELTERED GARDENS—HELONIOPSIS JAPONICA.

still far from common. The plant is perfectly hardy and can readily be increased by careful division of the short, horizontal rhizomes. The lanceolate, evergreen leaves are arranged in loose rosettes from which rise in April or May sturdy stems, carrying loose clusters, of up to about ten in number, of somewhat bell-shaped flowers which may be pink or soft rose in colour. The effect of a good group of these is highly attractive, and a position protected from the sun until well after midday should be selected for this handsome plant. An open position on the outskirts of the bog garden, where it succeeds very well, or a sheltered dell in the rock garden with a westerly aspect, would suit it where no woodland garden is available. The plant is not at all difficult under conditions as indicated, and only needs to be better known to become popular with hardy plant lovers.—W. E. TH. I.

V. M. II. AWARDS.

I WAS very pleased to read "Senex's" tribute to Mr. John Fraser (page 155). I was introduced to him a few years ago at an R.H.S. Show, but had no idea who or what he was. I have met him

again on subsequent visits to the R.H.S. Hall, when he has been most kind in answering and explaining things asked by an ignorant amateur. I have never met anyone who knew so much about horticulture all round as Mr. Fraser does. I am so absolutely an "amateur" that I do not know what V.M.H. stands for—but if it is "Veteran Master of Horticulture" it is fittingly bestowed on Mr. John Fraser.—ANNE AMATEUR.

WHAT IS A "HARDY" ANNUAL? A GENUINE GRIEVANCE.

I HAVE a complaint to make (not a "grumble"—to grumble, according to a dictionary definition, is "to complain without cause"). I made out my list of hardy annuals, so called! in several leading seedsmen's catalogues (having only one very small hot-bed reserved for a few half hardy and tender annuals). When the seed packets arrived, imagine my dismay in reading directions on several: "Raise in gentle heat"; "Sow in a hot-bed in February," and so forth. Now, I ask, is this fair of the seedsmen? I do not consider it cricket on

their part. If these so-called "Hardy" annuals require to be raised in heat, wherein do they differ from half-hardy ones, such as Stocks and Asters? Here I am "landed" with a lot of seeds which are of no earthly use to me! I think it would be only fair if I were to send back the packets to the vendors and request the return of my scanty spare cash—the seeds having been wrongly described as hardy in the seed lists. I am feeling extremely ill-used on this matter. Now, Messrs. Seedsmen and Sons, what have you to say to allay my rightful wrath? Since writing the foregoing THE GARDEN, April 1, has arrived, and among the unusual annuals I am delighted to find four I have just ordered "on spec," to wit, Cnicus coccineus, "Flora's Paint Brush"—what a nice old-fashioned sounding English name; the ruby dwarf variegated Nasturtium, and I have ordered the white one also; Schizopetalon Walkeri (for my fragrant border) and Nicandra physaloides Fearsome names!—which I hope will help to form a summer screen in company with Hemp, and two or three other tall things behind a garden bench. Have these two latter any English names? Please someone do tell me

if they have. In the description of *Salvia Horminum*, Blue Beard, methinks I recognise my old country cottage garden "Purple Clary," and if I rightly remember there were also red and white Clary; am I right? Most of the other unusual annuals I have grown or known, but having no rock garden I do not want them here.—A. A.

EUCRYPHIA PINNATIFOLIA IN SCOTLAND.

I READ your note (page 154) on this shrub with great interest. Such a wonderfully hardy shrub should be grown more often. Here, in Forfarshire, by no means a mild climate, we have a very fine specimen. It is planted in ordinary soil in an open bed with no protection, though the house cuts off the north. I think people must often fail with it from want of patience. Here it was six years before it flowered and we several times thought of digging it up. It flowered for the first time in 1910 and then our waiting was rewarded. The shrub grows so strong, it is almost a tree and we have to keep it within bounds. This is mostly done by cutting the flowers, which last very well in water. The shrub has a further merit, as it flowers in August when most things are over. It has always ripened its seed here and we have raised it very successfully. We would exchange the seeds of *Eucryphia pinnatifolia* for seeds of any other uncommon hardy shrubs.—MAY NOEL, *Pitkerro House, Kingennie, Dundee.*

A LOVELY STONECROP.

I WAS pleased to see a note on *Sedum brevifolium Pottsii* in THE GARDEN of April 1 (page 158), for it is a special favourite here and one well worthy of wider attention. Like many other *Sedums* the colour appears to vary considerably according to season, climatic conditions and probably soil. In this garden quite one of the most attractive features of the plant is the clear, almost electric blue which invests the mealy covering of the leaves during winter. In Mr. E. C. Buxton's garden at Bettws-y-Coed there is a natural pyramid of slatey rock covered with this lovely variety, forming one of the most attractive objects in a garden full of good and interesting things. In this instance the *Sedum* is rooted in the lichenous chinks of the hot southern face of the rock, but that it will do in a cooler medium is proven by the way it flourishes with us on some moss-covered stones. It is also grown on the flat in very well drained, gritty soil in association with the *Kaonias* and other lowly plants. Here, as elsewhere, it propagates itself freely by rooting the tiny sub-globular leaves which fall off the stems.—A. T. J., *N. Wales.*

SHOULD WE KILL WASPS?

WHAT have gardeners to say when a learned professor, backed up by a popular daily paper, tells the great B.P. not to kill wasps—not even queens? (This in addition to some wonderful hints as regards spraying and advice to the Ministry of Agriculture that the latter should issue instructions regarding certain insect pests which have been issued years ago!) To my mind wasps are among the most undesirable of insects, dangerous as well as unpleasant, and a source of great loss to fruit growers, especially when their numbers are excessive. Moreover, they are creatures whose habits are hardly less filthy than those of house-flies. That they do destroy a few of the latter (as the professor has discovered), has been common knowledge for at least 200 years, but that alone is not sufficient to exonerate them for their evil doings. Even the common fly has some quite desirable and useful attributes, but we do not spare its life on that account.—N. WALES.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Seakale.—The thongs selected as advised in a previous calendar should be planted on a well cultivated and open plot of ground. The rows should be about 20 ins. apart and the thongs about 15 ins., keeping the crowns slightly below the surface. If slugs are troublesome place a ring of ashes around each head.

Turnips.—See that a good breadth of these are sown, so as to follow the small early supplies from frames and warm borders. The drills should be 15 ins. apart, and the young seedlings thinned out in good time, allowing from 6 ins. to 8 ins. from plant to plant, according to strength of variety. This is essentially a vegetable where a quick growth makes the roots more acceptable, so encouragement should be given by hoeing frequently and watering during dry spells.

Runner Beans.—It is perhaps hardly wise or practical to risk a large sowing of this vegetable before early May, but it is certainly worth trying a few. At the same time sow a batch in 60-size pots and allow germination to take place in a frame. Pot on into 48-size pots when ready, and grow the plants sturdily until all danger of frost is gone, then plant out in well-enriched soil, 18 ins. apart in the row. A strict watch must be kept for slugs during the plants' early stages of growth.

Dwarf French Beans.—These, in company with the Runner Beans, are easily injured by frost, and large sowings should be delayed for another fortnight. A small sowing, however, should be made in a warm spot in light soil, and care taken that a batch of sturdy plants will be available from boxes at the end of the month or early May ready for planting out.

The Flower Garden.

Evergreen Hedges.—The majority of these require at least one trimming annually, and the present offers a suitable time for such as Holly, Box, *Thuja* and the Laurels. The Yew is always best dealt with during the latter part of July and early August. Should it be desirable to give a close and even trimming, the work must be carried out with a pair of shears, but a much more natural appearance is attained when the secateurs are used. The *Thuja* hedge especially should be thus dealt with, and I think it is but seldom anyone would use other than the knife or secateurs in dealing with Laurels.

Lawn Verges.—The care of these should always be considered, for when well kept they undoubtedly add a great deal to the appearance of the grounds. It may be found necessary occasionally to use the edging-iron, and such work should be done now at the commencement of the mowing season. The shears, used regularly and before the grass is allowed to grow too long, will easily maintain a firm verge outline for the remainder of the season. Verges lacking in vigour, and those that are mossy and impoverished, should be dressed at once with a good lawn manure, repeating again in a fortnight's time.

The Hardy Fruit Garden.

Vines on walls and buildings in warm positions are very active, and it will be necessary if the prospective crop is to have a good start that disbudding be undertaken in good time. While overcrowding must be guarded against, it is, I think, always advisable in dealing with Vines in such positions to ensure a fair covering of wood. The laterals selected for fruit bearing should be stopped at a couple of leaves beyond the bunch, and all subsequent sub-growths kept pinched also.

Fruit Under Glass.

Muscat Vines in Flower.—During the next few weeks many Vines will be in flower, and the success of the crop depends to a great extent on the treatment given at this season. In some gardens it is almost as easy to obtain a good set of Muscats as Hambros, but it is equally true in other gardens it is sometimes most difficult to obtain a satisfactory one. A great point to bear in mind is consistency of treatment; thus, should it be the aim of the grower to flower the Vines in a night temperature of 70° to 72°, this should be gradually reached and not immediately raised to this figure in a big leap. Again, if the treatment is to keep an entirely dry atmosphere during flowering time, less moisture should be given for a short while before that stage is reached. One of the main factors in securing a good set,

whether of Muscats or others, is to make sure of a good root action and see that the borders are just nicely moistened through before flowering commences. As a few aids in trying to make sure of a free setting of berries, carry out all necessary stopping of shoots a couple of days before, so that none will be necessary during the time of flowering. Do not tie down the shoots until afterwards. Arrange matters so that plenty of light and air reaches all bunches, and between 10.30 and 12.30 go lightly over all bunches with a rabbit's tail with pollen from a free setter, if such be available. It is perhaps hardly necessary to add that fluctuations of temperature and cold draughts must be avoided.

H. TURNER

(Gardener to the Duke of Northumberland).
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Broad Beans.—Sow goodly quantities of the long-pod varieties now. As this popular vegetable is always in demand, more especially is it desirable to provide pods of tender young Beans throughout the season, and this can best be done by successional sowings. Sow in double rows 2½ ft. apart, and keep the soil well cultivated between the rows. In wind-swept gardens stakes should be inserted at intervals in the rows, and binder twine run down either side as a support.

Turnips.—Make further sowings of Early Milan varieties, so that a fresh and constant supply of roots may be maintained. Early Turnips are often attacked by the fly, so should be dusted with soot or wood-ash as a preventive.

Brassicæ.—Sow in the open border autumn and winter varieties of the Brassica family, including Borecole, Autumn Giant Cauliflower, Savoys and Veitch's Self-protecting Broccoli.

Celery.—Sow seed of Celery for late planting, and prick out earlier sowings into boxes or frames. Use a rich compost, and place a layer of well rotted dung in the bottom of the boxes, or under the layer of fine soil in the frames. Given this treatment the plants lift with fine roots when being transferred to the trench.

Tomatoes.—Pot on the various batches before they become pot-bound, and place on a shelf near the glass. Avoid too high a temperature, and admit air freely during sunny weather. Cold draughts must be guarded against, as there is nothing more detrimental to the welfare of young Tomato plants than a current of chilly air.

Carrots.—The principal sowing of Carrots may now be made. Choose a day when the ground is in good working order, and sow in shallow drills 12 ins. apart. In many private gardens the intermediate varieties are most favoured, and in this class we find Austin's Exhibition one of the best; it is practically coreless and of superb quality. Long Red Surrey is a reliable long-rooted sort and specially suitable for late keeping.

Potatoes.—Continue with the planting of second early and maincrop varieties. Abundance, British Queen, Great Scot and Arran Comrade are first-rate second early sorts. Arran Victory (purple skin), Crofter, King Edward and Kerr's Pink can be depended upon for maincrop.

The Hardy Fruit Garden.

Raspberries.—If unable to top-dress with organic manure, a dusting with some kind of artificial stimulant will greatly benefit. Hoe it lightly in, and the spring showers will take it to the fibrous surface roots.

Peaches on Walls.—Where these are in flower they ought to be protected at night from late frosts by hanging a double ply of fruit netting in front of them. A few bent Willow shoots placed through the branches will keep the net from becoming entangled in the foliage or from damaging the blossom.

The Flower Garden.

Kniphofias.—Beds of these in the shrubbery or flower garden should now have the surface soil stirred up and given a mulching of rich farm-yard manure. The more tender sorts, which have been wintered in cold frames, should now be placed in their flowering quarters.

Buddleia variabilis magnifica.—Plant out fresh rooted stock of this desirable plant which has been grown on in pots. This variety is particularly adapted for covering walls or for grouping in the shrubbery. It has also a pleasing

effect when planted in the herbaceous border, cutting it back annually in spring.

Chimonanthus fragrans should now be spurred back, so that fresh and well ripened shoots may be produced for next season's flowering. Although not always fortunate in escaping severe frosts, its peculiar yet fragrant flowers are a source of delight during February and early March.

Herbaceous Borders should now be forked over and cleared of any protecting material used during the winter. On light, gravelly soils a heavy surface dressing of well rotted leaf-mould or cow dung should be given, and this will prove of inestimable value to many of the less robust plants should the summer be hot and dry.

Violets.—Plants flowering in frames during the winter should now be lifted, and strong single crown runners taken off and planted in a partly shaded border. Incorporate plenty of well decayed dung and leaf-mould with the soil. Plant the runners in lines 15 ins. apart and 12 ins. apart in the rows. Keep a sharp look-out for signs of red spider on the young plants, and spray in the evening with soot water on its appearance.

Lawns.—Growth is now noticeable on lawns, so have them well swept and rolled in readiness for the use of the mower. Edges may with advantage be pared now with the edging-iron, as this facilitates the work of clipping during the rest of the season. Return any bare patches, or should there be difficulty in obtaining fresh turf, sow lawn grass seed and give a dressing of sifted soil to assist germination.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Celosias in successional batches are very useful for furnishing the greenhouse throughout the summer and late autumn months. It is true that *Celosia cristata*, the Cockscomb, is not by any means a graceful plant; still, it always attracts attention on account of its extraordinary form. On the other hand, the variety *pyramidalis* is certainly more graceful, and well grown plants last a long time in good condition. In growing *Celosias* it is very important to get a good strain, for, in the case of this plant, no amount of good cultivation will improve a poor strain. Here I may say the same applies to Balsams: hence the importance of getting seed from a firm of repute. If not already done, the first batch of *Celosia* seed may now be sown in a temperature of 50° to 60°. When large enough to handle the young seedlings should be picked off into pots or pans, until they are large enough to be potted off singly into small 60-size pots, using a light rich soil during all the stages of their cultivation. It is very important to keep them growing steadily on without any check. Their final potting should be into 5 in. or 6 in. sizes, while some of the tall growing varieties of *pyramidalis* if well grown will require 8 in. pots, in which they should make fine specimens some 5 ft. in height. They are subject to attacks of red spider and Begonia mite. The former can be prevented by a free use of the syringe, and the latter by the use of Campbell's sulphur vaporiser.

Winter-flowering Begonias, of the types resulting from crossing *B. scottrana* and the tuberous-rooted varieties, generally prove very troublesome to bring safely through their resting period. In this respect they differ from both parents, owing to the fact that they must never be really dried off altogether, but every effort should be made to retain a portion of their old foliage until they show signs of starting into fresh growth. They should do this during the month of April, and at this time they may safely be turned out of their pots and the balls of soil slightly reduced so that they can be repotted into the same size or even smaller pots, using for this purpose a light rich compost. When repotted they require very careful watering until they have made fresh roots; rather should they be encouraged to grow by frequent damping between the pots and light spraying overhead. In a moist genial temperature of some 55° they should grow away and in due course give good strong cuttings. Cuttings that were struck late last year may be grown on for flowering, such examples usually making fine large plants. A few of the best varieties are *Optima* (this in some ways the best of them), *Exquisite*, *Emita*, *Fascination*, *Elatior* and *Mrs. Heal*. There are several double and semi-double varieties, but in the immediate neighbourhood of London it is useless to grow them, as one night's fog is sufficient to strip them of every flower.

Vallota purpurea.—For some obscure reason one seldom sees this beautiful plant in good condition in gardens, whereas fine specimens in perfect health are frequently seen in cottage windows. This plant very much resents frequent disturbance; thus, when well established and in good health, it should be left severely alone, except for detaching some of the numerous offsets it produces so freely. If it is desired to increase the stock the largest of them may be potted up, putting three or four bulbs, according to size, into a 5 in. pot. The plant is really evergreen and should never be dried off entirely, although during the winter months it should be kept on the dry side. At this season, however, they will require more water at the root. They should not at any time be given a high temperature; a cool greenhouse, or a frame from which frost is excluded, suits them very well.

Nerines should be given a light position well up to the glass in a cool house or in frames. They should, by watering and feeding, be encouraged

to retain their foliage in a fresh condition as long as possible, for it is only by this means that good results can be expected from them. As their foliage shows signs of dying off, water should be gradually withheld, finally leaving them exposed to the sun, without any water at the root until August and September, when they should flower and commence growing.

Lobelia tenuior.—This beautiful *Lobelia* should be grown in successional batches for the greenhouse. Being of a slender habit it is best grown four in a pot, and it makes a better plant if it is pinched once or twice in its young state. If grown on into 6 in. pots really fine specimens can be produced, but it is by no means the easiest of annuals to do really well and requires careful watering at all times. However, it is really worth some extra attention, as good blue flowers generally find plenty of admirers. It is best grown at all times in a cool greenhouse, or low pit, where it can be kept well up to the glass.

Royal Botanic Gardens, Kew.

J. COULTS.

PEAT PLANTS THAT WILL DO IN LOAM

Given a lime-free soil and situations suitable to the particular species, there really are very few hardy plants which require peat for their successful cultivation.

SETTING aside the Heaths, Azaleas and Rhododendrons, there are many plants usually listed as peat-lovers which will do admirably in ordinary, but cool, lime-free woodland loam, with the help, in a few instances, of a little leaf-mould.

Take, in the first place, the so-called *Andromedas*. Some half a dozen of the more lowly species, among which may be specially mentioned *Zenobia speciosa*, *Leucothoe Catesbaei* and *acuminata*, have taken kindly to the above conditions here and annually reward us by wreathing their elegantly curved stems with their large waxen bells. The true *Andromeda polifolia*, the bluish foliage of which harmonises so pleasantly with its purple flowers, is also quite at home in the half shade of the thin woodland. When it is possible to do so, all these are so planted that they are in a line with the eye, otherwise the flowers, which are generally suspended underneath the branches, are not seen to best advantage. The most severe drought does not appear to affect these shrubs, once they are fairly established; and no pruning is ever done beyond cutting out old flowering wood, which has a habit, possibly a natural one, of dying back.

With *Cassiope tetragona*, however, I admit we have had some trouble. New plants have flourished for a season or two, studding their curious Club-moss stems with Lily of the Valley flowers, and then languished. What this fascinating little thing asks is doubtless a uniformity as well as a sufficiency of moisture, not only at the roots (which must have perfect drainage), but in the air, along with partial shade. But even in a garden of moderate dimensions one is generally able, by trying different sites, to hit upon the peculiar requirements of a plant without those requirements being always apparent. Thus our latest colony of *Cassiope*, in a hitherto untried situation, is showing sufficient promise to encourage efforts with its lovely relation *fastigiata* and others.

Of the *Pieris* group, the well known *japonica* and *floribunda* flourish like the proverbial "green bay tree," the former rather too well for its blossoming reputation. But, good as these are, the gem of the genus is undoubtedly *P. formosa*, which went away from the first, making a sturdy bush of some 5 ft. in height. Though not tender, this splendid species has given disappointment, or perhaps I should say has, with some, earned a reputation for disappointing, owing to the belief that its flower buds, if not the blossoms, are apt to be injured by frost in the early months. Our

experience is, however, that this is a very variable plant in regard to its date of blooming, the large sprays of big white globes appearing at any time from January to May, but usually not until they are fairly safe. Moreover, these flowers are, unlike those of the other species mentioned, nearly always so produced that they derive considerable shelter from the overlapping Rhododendron-like leaves. The wonderful colour and gloss of the new growths, a highly burnished coppery-crimson, are in themselves sufficient to give *P. formosa* high rank among the best of shrubs.

The true *Ledums* we have not had long enough to justify one making any definite declaration as to their adaptability to (comparatively) "dry" treatment, but *L. latifolium* certainly promises great things growing in loam at the foot of the Heather slope. Of *Leiophyllum luxifolium*, however, which comes near to these, we have nothing but admiration. It is an easy-tempered, healthy little shrublet, doing well almost anywhere. Its close-set foliage of small Myrtle-green leaves is speckled with bright red buds throughout early spring, these breaking into white flowers in April or later. Not unlike this to the casual glance is *Gaultheria trichophylla*, rather more "trailing" and more fastidious as to its growing medium, but one nevertheless which will thrive in a cool bed of leaf-soil and gritty loam. It appreciated a top-dressing of the same material in spring, and for this responds the more generously with its big turquoise berries, beloved of birds or mice—probably both. Of the other *Gaultherias* grown here, *nummularioides* is admirable at all seasons, sliding down a mossy slope, rooting as it goes, with *Linnaea borealis* for company and *Cornus canadensis* hard by. *G. Shallon* is perfectly content in the plain loam and does not grow too big; and not less satisfied are *procumbens* and *pyrolaefolia*, though the former is often slow to take hold. All these *Gaultherias* appear to like growing in association with something else, even if this is the natural thin herbage and creeping Ivy of the woodland bank, and they languish, as if from sheer loneliness, when isolated in the orthodox bed. This applies no less truthfully to *Galax aphylla*. A few odd roots of this "stuck in" among a drift of fallen leaves and native Ferns and forgotten have made a large colony, whereas those planted in the rock garden and elsewhere with the utmost care as to soil and aspect have remained about the same size for years. Grown well in suitable surroundings *G. aphylla* is a precious possession, beautiful at

all seasons, and fit associate for the stronger Shortias and other good things after their kind.

Like some dwarf *Euonymus*, a plant of *Pachystigma Canbyi* occupies a partially-shaded spot near *Epigaea repens*. This was very slow to start, as many of these things are, but if they are right who say it needs full exposure one error at any rate is in the situation. *Philesia buxifolia* may also be counted among the extremely cautious, and whether it will like its bed of leaf-mould and sand remains to be proven. It is certainly doing as well as many another specimen seen in the choicest of peat. Near this rather exclusive Chilean is a ramping mat of *Polygala Chamæbuxus*, both yellow and purple, which is in flower nearly the whole year round and which would be much more colourful did the mice not devour its bloom buds so persistently. Pretty and cheerful as this indispensable little woodlander always is, it can be secured in many forms, some being much superior to others in flower and foliage. *P. Vayredæ* is a dwarfier, but even more brilliant species requiring rather more sun and consideration in choice of situation.

The *Kalmias* do satisfactorily in a cool, shaley loam with the aid of a little leaf-mould. *K. latifolia*, best and biggest of the group, planted in that medium some years ago has seldom failed to flower, though it has hardly ever had any attention since. Not less beautiful is *Rhodora canadensis* which is covered with its gay little rosy-purple flowers before the end of March, and these seem to be able to withstand the most inclement of spring weather undisturbed. Our common Bog Myrtle (*Myrica Gale*) is quite happy in loam which does not dry-out too severely, and it is well worth a place for the sake of its fragrance. Though not a woodland plant, it will do in thin shade. Of *Vacciniums* I can say little, these wood and moorland shrubs not having been tried to any extent; but *V. corymbosum*, excellent in spring and autumn, and probably one of the best, is satisfied with our treatment, and the common *V. Myrtillus* (Bilberry) flourishes naturally in pure loam—and very dry rocky loam, too—in the woods near by. *V. Vitis-idea*, our native Cowberry, a better garden plant than the Bilberry, will also prosper under similar conditions.

Whether *Itea virginica*, a shrub of quite another order—a Saxifrage—will eventually reward us time will show, it being still in early youth, but it seems probable to judge by the progress it is making. After all, much of the delight of gardening is having things on the "waiting list," and one that is just emerging from that state by producing a cluster of pendent buds above its finely-cut foliage is *Bryanthus erectus*. *B. pilosa* (ferruginea) is also in this happy condition, and these twain, together with *B. cuspitriformis*, which makes fine mats and blooms abundantly (usually twice a year), are growing in a poor, crumbly mixture of shaley soil (mostly chippings) with a very little leaf-mould forked through at planting time.

North Wales,

A. T. JOHNSON.

Practical Gardening.—Though it gives no idea of the magnitude of the book, "Practical Gardening" is a fortunate title for this six-volume gardening encyclopedia. Many of the most eminent of present-day gardeners have contributed to the book, which appears to deal with every conceivable subject of interest to the garden-loving public. The work is copiously and, generally speaking, helpfully illustrated, but it is,

"Practical Gardening for Pleasure and Profit," edited by Walter P. Wright, The Educational Book Co., 17, New Bridge Street, E.C.4.

of course, the letterpress which is most important, and this is, on the whole, very satisfactory. Barring an opening chapter dealing with garden tools which seems rather purposeless, the essentially practical chapters are excellent, although the writer does not care for the sections dealing with garden planning and rock garden construction. This is a small blemish on a work of this character, for it is safe to say that few who would buy such a book would expect garden planning to be treated of. All the species of plants commonly met with in gardens are referred to, but the book makes no pretence to be a gardening dictionary.

Late Autumnal Flowers.—The specific name "syriacus" suggests that that shrubby Mallow *Hibiscus syriacus* is a native of Syria. It is, however, a wild plant of China and India, being only met with in Syria as a cultivated shrub. A free-flowering bush, in gardens where a selection of named varieties are grown these *Hibiscus* are one of the most valued autumn shrubs. They thrive in British gardens in all but the coldest positions, and in these localities they are worth giving favourable and sheltered positions against a south or west wall. Forming shapely and much branched bushes up to 8ft. or 10ft., sometimes more. Pruning is not desirable unless the positions where the shrubs are growing makes it necessary to limit their size. When this happens, prune in March or early April. The *Hibiscuses* thrive in most garden soils which are well drained. They benefit by the trenching and manuring of the ground previous to planting, and a mulching of decayed manure and leaf-mould may be given about midsummer with advantage. Cultivated in our gardens for more than three hundred years, a considerable number of varieties are grown with both single and double blossoms. Six of the best are *Cælestis*, purplish blue, single; *Hamabo*, bluish white, crimson base, single; *pulcherrima* white, crimson base, double; *punicus*, red, double; *Souvenir de Charles Lebreton*, lilac purple, double; and *totus albus*, pure white, single.

Dividing Border Chrysanthemum Stools.—Ofttimes it is not practicable or convenient to lift and store border Chrysanthemums through the winter months when the flowering period is over, but when re-making the borders it is found necessary to divide the plants up. The stool should be carefully lifted by means of a fork, and pulled apart with the hands, if this be possible. Failing this, two hand forks may be inserted together, back to back, and the stool levered apart, or in the case of a very stubborn stool a large pruning knife may be called into use, though it is preferable not to cut the roots more than is absolutely necessary. It is best to discard the centre, or older portion of the stool, retaining the younger and more vigorous outer portions, which can then be replanted in such a way as suitable. The best effect is obtained by planting three or five of these portions about 6 inches apart each way, thus forming a nice-sized clump in the border convenient for staking when growth is made.

FORTHCOMING EVENTS.

April 19.—Hertford Horticultural Society's Meeting.

April 20.—Manchester and North of England Orchid Society's Meeting. Midland Daffodil Society's Annual Exhibition (two days).

April 21.—Paisley Florists' Society's Meeting. Eastbourne Horticultural Society's Meeting.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

VIOLETS ATTACKED (H. M. W., Radnorshire).—The Violets are attacked by the leaf spot fungus (*Phyllosticta violæ*). Remove as far as possible all diseased leaves and spray the plants with liver of sulphur, 1oz. to 3 gallons of water, or dust them over with flowers of sulphur.

ANTIRRHINUMS ATTACKED (D. W., Suffolk).—The *Antirrhinums* are attacked by a fungus, which seems to be spreading rather rapidly during the past few years. It would be well to destroy the first plant showing the brown spots on the leaves and stems so as to stop its spread another year. Little can be done to much purpose now except to get rid of as much of the infected material as possible and to spray the rest of the plants with a solution of sulphide of potash, 1oz. to 3 gallons of water. We suspect that the Sweet Williams are not attacked by the same trouble but by another fungus belonging to the rusts and for this the removal of diseased parts and the spraying of the remainder with a rose-red solution of potassium permanganate is best.

ROSE GARDEN.

ROSE SPECIES FOR A LAWN BED (Woodvates, Wilts).—Under suitable circumstances the bush Roses as mentioned by our correspondent might be arranged to show the general effect from the windows or front door of the dwelling house, but the situation of the latter is not shown on the plan sent. The bed is also somewhat irregular in shape, and because there is grass all round it, the best plan would be to plant the tallest Roses in groups along the centre, so that the view from all sides will be the same. The situation is open so that the Roses will develop and bloom on all sides equally. They may be planted in groups of three, five or other number as our correspondent thinks fit. If the soil is good it would be well to give a space of 4ft. between every two of *Rosa sericea pteracantha* (6ft. to 12ft. high), *R. Pratti* (6ft. to 8ft.), *R. Moyesii* (6ft. to 10ft.), and *R. rubrifolia* (5ft. to 7ft.). There is a white *Polyantha* Rose named *Hélène* (6ft. to 10ft.) which should also be central or in the middle of the bed. *R. nitida* and *R. n. flore pleno* grows only 2ft. to 3ft. and should be near the outside. Other Roses we would suggest are *R. Hugonis* (5ft. to 8ft.), *R. alpina* (6ft. to 8ft.), *R. alba* (6ft. to 8ft.), *R. spinosissima altaica* (3ft. to 6ft.), *R. cinamomea* (6ft. to 9ft.), *R. lutea* (3ft. to 5ft.), Sweet Briar (*R. rubiginosa*, 4ft. to 8ft.), and *R. rozosa* or any of its varieties (4ft. to 6ft.). All of the above should be planted 4ft. apart, except *R. nitida*, *R. Hugonis* and *R. alba*, which grow erect. The others we suggest are more spreading as they get large and it would hardly be possible to get into the individual groups without thinning or shortening of the shoots, which would spoil their natural beauty. Of course, if planted thickly they keep one another more erect. Bearing in mind last year's drought, we should prefer to plant in the autumn.

THE GREENHOUSE.

BEGONIA OPTIMA UNSATISFACTORY (R. W. D., Basingstoke).—We find no disease in the *Begonias*. It is possible that the soil is sour and that the roots have suffered from this cause, when in spite of watering nothing could be done to save them. Avoid over-potting and use fresh soil in future.

TREES AND SHRUBS.

SUITABLE TREES TO PLANT ON A GRAVE IN FRANCE (E. E. B., Surrey).—If our correspondent can get a tree of the Japanese Maple (*Acer palmatum dissectum atropurpureum*) in a pot, it could be planted in the Arras district early in May. If taken from the ground then it would be starting into growth, and the lifting would cripple it. If obtained now and potted up our correspondent could take it to Arras in the pot and replant it without disturbing the soil. Well water it the day before turning it out of the pot, or the day on which leaving this country. White flowered shrubs that would be suitable are *Philadelphus rosæ* (3ft.), *P. vici lactæ* (3ft.), *Olearia Haastii* (evergreen, 3ft. to 4ft.), *Viburnum plicatum* (3ft.), and *Hydrangea paniculata grandiflora* (3ft. to 4ft.). Whichever of these are decided upon, it would be safest to pot it up now.

MISCELLANEOUS.

THE IRIS LEAF MINER (A. E. C., Pa.).—This is the grub of a small two-winged fly, *Agromyza atea* (A. iræos). It attacks various Irises, but especially perhaps *I. ochroleuca*. Another species, *A. latorella* is reported a serious pest of *I. Kampferi* in New Jersey. The female fly deposits her eggs on the leaf and the grub burrows in, feeding on the soft tissue of the leaf, and later becoming a pupa in the burrow. Where only a few leaves are attacked they should be cut off and burned, or the foliage should be cut down and burnt in a tannin. Spraying with nicotine soap emulsion would probably kill the larvae in the burrows so long as the spraying was not put off too long. In England a small green parasite kills many of these grubs.

NAMES OF PLANTS.—L. J. G., Ireland.—Probably *Narcissus minimus*. The specimen sent was absolutely shrivelled up so could not identify correctly with certainty.

[APRIL 22, 1922.

COLOUR IN THE ROCK GARDEN

ROCK plants, especially those properly classed as alpine species—not confining the word "alpine," by the way, to the European range we call the Alps—are readily established at almost any season, since they are supplied in pots. This notwithstanding, the present is a particularly

good season to purchase, as many sorts are readily propagated shortly after blossoming.

We will endeavour to point out the species and varieties most worthy of cultivation and their individual requirements as to "exposure," soil, and such like. Almost every gardener, reading "showy and accommodating plants" will

have mentally envisaged the varieties of *Aubrieta deltoidea*, *Arabis albida*, *Alyssum saxatile* and *Iberis sempervirens*, and assuredly, these four species form, as it were, the very foundation of a showy rock garden.

To select the best varieties of *Aubrieta deltoidea* is not easy, but the following cover the full range

A FINE EXAMPLE OF HAPPY PLANTING IN THE ROCK GARDEN.

of colour and are all first class; D. Mules, with deep violet-purple flowers, is, though quite an old one, still the best of its colour. Among the "crimson," Fire King and Leitchlinii are recommendable; there is no better soft rose than Moerheimi, while Bridesmaid, bluish-white, is very neat and extends the colour range. There are numerous lavender sorts, but none, so far, so effective as the very old græca. For those who like "new friends" we would recommend Lilac Queen, Lloyd-Edwards (a very large-flowered violet-purple), and Violet Queen.

As regards *Arabis albidæ*, both single and double forms are often useful for places where little else will grow, and the single one, though it spreads rapidly, is more compact and less straggly than the double one.

The soft pink *Arabis aubrietoides* is, though quite easy, an infinitely choicer and more beautiful plant than either.

There is a variety of *Hieris sempervirens* called Little Gem, which is in habit of growth quite compact and globular, and is both neat and beautiful. Still, for "bold" effects the typical plant, or the closer-growing Snowflake, is very useful.

Alyssum saxatile, as one of the brightest and most cheering spring flowers—its yellow has that dash of orange in it which gives "warmth"—may be more freely used. There is a desirable closer-growing form—compactum—a very lasting double form, and an entirely pleasing lemon-yellow variety called citrinum. The saffron-yellow *A. gemmonense* is a useful plant often confused with the last-named *Lithospermum prostratum*, with its flowers of purest gentian-blue is an excellent plant, also the pretty azure blue variety Heavenly Blue.

Some of the brightest masses of colour in the rock garden are produced by the varieties and hybrids of *Phlox setacea*, and remembering that it is "colour" we are seeking, let us first select Vivid best described as "hot salmon" colour a wonderful sight when in flower; G. F. Wilson (syn. lilacina), slate blue; compacta, rose with very little blue in it, and The Bride, a beautiful pearly white. Other good varieties are Brightness, Kathleen and Daisy Hill, all rose-coloured sorts; Fairy, a compact-growing, neat plant, with greyish lilac flowers, and Newry Seedling—in the way of G. F. Wilson but paler and of a looser habit of growth.

All the foregoing suffer from biting winds in winter and are best planted with shelter from the north and east and with a warm exposure, so that they may ripen their wood. They should be propagated by division or from cuttings. Either operation should be performed as soon as they start to make fresh growth after flowering.

Phlox amena, a pretty, early-flowering, rose-coloured species with numerous androsace-like heads of bloom, makes a brave show; so, too, does the taller-growing *P. canadensis*,

A CHARMING COLONY OF ONE OF THE HOOP PETTICOAT DAFFODILS (*N. BULBOCODIUM CITRINUS*).

THE LADY'S SLIPPER (*CYPRIPEDIUM SPECTABILE*).

with pretty, slaty-blue flowers. The variety *Laphami* is, perhaps, the most recommendable; its flowers are sounder and a shade deeper in colour than those of the type. There is also a pure white form.

Phlox ovata, something like a dwarf rose-coloured *Border Phlox* (*P. decussata*), with neat and leathery ovate foliage, is also useful, and easy, for not too choice a corner.

The double form of *Lychnis Viscaria* gives a mass of dazzling rosy-carmine, while its neat, sturdy habit makes it very suitable for the rock garden; but, like the *Crimson Rambler Rose*, it is somewhat of an *Ishmael* in the garden, owing to its propensity for making even really bright flowers look dowdy.

The *Welsh Poppy* (*Meconopsis cambrica*) is a very "easy" plant and, especially the double form, very showy and beautiful. Their distant cousin, the smaller *Bleeding Heart* (*Dicentra eximia*), with its pretty lacinate foliage and purplish rose flowers, should also be included.

Of the Pink family (*Dianthus*), the following are of easy culture and beautiful: *D. atrorubens*, with dark grassy foliage and deep red glomerate heads after the way of the *Sweet William*; the *Cheddar Pink* (*D. cæsius*), rose-coloured, very fragrant; *D. fragrans*, deeply fringed creamy flowers with a powerful and pleasing odour; *D. superbus*, which might almost be described as a rose-coloured form of the last.

Of a totally different habit of growth to those previously mentioned, and rather later flowering, the *Maiden Pink* (*D. deltoides*) and the closely related *D. graniticus* are two useful small-flowered deep rosy-red kinds, very floriferous, and with neat glossy dark green foliage.

Two double garden hybrid forms, *Salmon Queen* and *Napoleon III.*, are also beautiful and of striking coloration. The latter is a very brilliant crimson, but, if not carefully handled, has a tendency to flower itself to death.

The prostrate *Gypsophila* (*G. repens*), with its pretty glaucous trailing foliage, star-bespangled, must on no account be overlooked. The form *monstrosa* has larger flowers and less trailing habit, and *rosea* has pale rose flowers with the habit of the type. Another pretty species is *G. Sundermanni*, with bright lilac-rose flowers.

Owing to their very trailing habit of growth it will probably be better to separate the *Sun Roses* (*Helianthemum*) from their cousins, the *Cistus*, and deal with them in this section. They are, without exception, beautiful and gay-coloured plants, with pleasing foliage, quite unexact as to soil, but liking plenty of direct sunlight. All the kinds are worthy of cultivation, but we have a partiality for *Mrs. Croft*, *Salmon Queen*, *Brilliant* and *Rose Queen*, and in general the single forms are preferable to the double ones.

Two species of *Speedwell* (*Veronica*) come into this class—*V. repens*, with masses of slaty-coloured flowers, and *V. rupestris* (syn. *prostrata* and *Tencrium dubia*), with masses of bright blue flowers in zinc spikes—a very old and very beautiful plant. There is a white form of this species, also a yellow foliaged one (*Trehane*).

A very beautiful plant for a sunny corner is *Helichrysum bellidioides*, a quickly spreading species, with grey foliage and white immortelle-like flowers most profusely borne.

Many of the alpine species of *Silene* make a brave show, and two of them are extraordinarily accommodating, these being *S. alpestris*, with glistening snow-white flowers, and *S. Schafta*, producing purplish rose flowers at mid-summer. There is a tiny *Golden Rod*—*Solidago prostrata*—which makes a welcome splash of colour very late in the season. Some of the prostrate *Thymes*

are among the loveliest of creeping rock plants, such are *T. lanuginosus*, forming patches of silky grey foliage, and which is rather disfigured than otherwise by the pink blossoms; *T. Serpyllum coccineus*, with bright crimson, and *T. S. albus*, with white flowers. These two should sometimes be planted together, as the combination is very pleasing.

Many of the *Campanulas* are among the most amenable and beautiful of rock plants. Very good and easy are all the forms of and crosses between *C. carpatica* and *C. turbinata*, as are *C. barbata*, *C. sarmatica*, *C. pusilla* and varieties, and *C. Portenschlagiana* (syn. *C. muralis*).

In a shady corner, even under trees, the *Astrantias* will succeed. These are among the most beautiful and refined of umbelliferous plants.

An effective plant for sun-parched slopes is the *Rock Purslane* (*Calandrinia umbellata*). Its crowded blossoms are a fiery magenta-crimson.

BOLD PLANTING AND ITS EFFECTIVE RESULTS.

This is not a long-lived plant, but is, fortunately, easily raised from seed.

A very showy, if rather coarse habited class of hardy trailing foliage plants, is the *Mouse-eared Chickweed* (*Cerastium*). Quite the best with silvery foliage is *C. tomentosum*, smothered, in spring, with fair sized white flowers reminiscent of the *Greater Stitchwort*.

Useful plants for crevices in the rock cliff or for dry walling are the alpine *Erinus* in three colours, the typical plant with reddish-purple, albus with white, and carmineus with rosy-carmine flowers. For the same purpose, too, we have the pretty golden *Hedge Mustard*, *Erysimum pulchellum* (syn. *rupestre*).

Just a few of the smaller *Torch Lilies* (*Kniphofia*) are suitable for the rock garden, and give a much to be desired variety of form, such, for instance, as *K. paniciflora*, with yellow, *K. Macowanii*, with pinkish-coral blossoms, and *K. corallina*, with almost scarlet spikes; while, for the larger background, *K. rufa*, and even stronger-growing kinds may be made use of. It is scarcely necessary to mention that all *Kniphofias* need protection from hard frost, particularly frost following wet.

The perennial *Flaxes* are useful for the rock garden, especially the dwarf *Linum alpinum*, but even the species of *L. perenne*, or *L. narbonneuse*, will look in no way out of place.

For the shadier positions some of the *Monkey Flowers* (*Mimulus*) are very suitable; such are *M. Burnettii* and *M. cupreus Brilliant* with bronze, *M. cupreus Coronation* with carmine, and *M. cupreus Scarlet Queen*, a variety with almost scarlet flowers.

Aster alpinus is quite a showy plant, and there are several excellent varieties of various shades of colour. Among the *Yarrows* (*Achillea*) are to be found several carpeting plants with grey foliage and pleasing flowers. Among the best may be mentioned *A. argentea* and *A. Huteri*, with grey, and *A. Kellereri* and *A. rupestris*, with green foliage; all of these have white flowers, while *A. tomentosa* is a free-flowering yellow species.

Of the *Bugles* (*Ajuga*), the only ones really worth growing are the beautiful blue *A. Brockbankii*,

and perhaps the prettily variegated *A. reptans variegata*. Two of the *Sandworts* (*Arenaria*) should be found in every rock garden—the glorious white trailer, *A. montana*, and *A. balearica*, which covers the stones with minute trails of bright green foliage studded with tiny starry blossoms. The habit of the last-named plant recalls to mind that beautiful minute-eling *Willow Herb* (*Epilobium Hectori*), with bronze foliage, inconspicuous flowers and cottony seedpods.

Some of the *Ethionemas*, especially *A. pulchellum* and *A. grandiflorum*, are mass effect plants, and planted with a south aspect, or, better still, built into the joints of the cliff face, so that their crowns lie sideways, in nice gritty soil, will flourish. A newer very beautiful form is *A. armenum Warley Rose*. *A. coridifolium*, sometimes confused with *Iberis jucunda* is worth growing with its neat habit and grey-pink flowers.

The plants dealt with above have, except for a general liking for a well drained sweet soil, and, sometimes, a partiality for some particular exposure, required no special cultural attention. They do not, of course, exhaust the list of desirable plants for the rock garden.

DISTINCTIVE TREES AND SHRUBS

Now that economy in the garden is the order of the day, the planting of trees and shrubs is on the increase. The following article furnishes suggestions of beautiful ornamental trees and shrubs which should find a place in the average garden.

A TREE may be distinctive on account of its flowers or leaves, or both. It will also appeal to the imagination if uncommon or scarce; and those who love trees for their own sakes will give these their due consideration and attention if they succeed in their gardens or grounds under the conditions available. Trees of unusual dimensions are the pride of their owners, even if common, but much more so if they are rare. Those I intend to discuss are not notable for great size, but possess some outstanding characteristic that makes them desirable in gardens of moderate dimensions.

The Maidenhair Tree (*Ginkgo biloba*) makes a spire, erect tree that may ultimately reach a great

succeeded by three-angled seedpods that remain on the tree for some time after the leaves have fallen, and being 1½ ins. to 2 ins. long are highly conspicuous. Trees 12 ft. to 30 ft. high flowered very freely in 1911 and 1921. They flower more regularly in France, where the summer is warmer than ours. The Sweet Gum (*Liquidambar styraciflua*) resembles a Sycamore to some extent, but is of narrow, upright habit and becomes highly conspicuous in autumn when the leaves assume their crimson and orange hues. The crimson and golden tints of the dying leaves of *Parrotia persica* are the special feature of this tree; but the red anthers of the flowers make the leafless tree conspicuous on sunny days during February or March, so that it ranks as a late

on the outer face, white on the inner, and often 4 ins. long and as broad. As they are fleshy in character they form a massive and shapely bloom. This hybrid is said to have arisen by chance, so that the second parent may have been *M. obovata purpurea*. The most popular of these hybrids is *M. Soulangeana*, which may be seen in many gardens, where it is the most conspicuous object during late March and April.

The Laburnums are delightful trees when they come into bloom. A natural variety, named *Laburnum vulgare Alschingeri*, has racemes of flowers 9 ins. to 12 ins. long and flowers very profusely, making a handsome tree. When growing vigorously, *L. Vossii* has racemes twice as long. It is a hybrid between the common and

THE FREE FLOWERING JAPANESE CRAB (*PYRUS MALUS FLORIBUNDA*).

height, without casting much shade on other objects, and withstands smoke well. The two-lobed leaves, both in form and venation, bear a strong resemblance to the lobes of the fronds of a Maidenhair Fern. Indeed, a Japanese botanist some time ago discovered that it is intermediate between the Ferns of geological times and conifers. Several species of *Ginkgo* at one time existed from the Island of Mull to China. Now the above is only known as a planted tree in the vicinity of Chinese temples, and the trees cultivated in the old and new worlds are descendants from them. The soft uniform yellow of the dying leaves in autumn is very handsome.

Koe'reuteria paniculata is related to the Horse Chestnut and Sycamore, but has much divided leaves and large panicles of small yellow flowers,

winter flowering tree. Last year's sunshine made it bloom profusely everywhere this year. In summer it bears some resemblance to a Beech. The Kentucky Coffee (*Gymnocladus canadensis*) appeals to us entirely by its leaves, which are bipinnate, or twice divided, and may reach a size of 3 ft. long and 2 ft. wide. The habit of the tree is stiff and ungainly when the leaves are down, but the few trees in cultivation are highly cherished by tree-lovers. The Mop-headed Acacia (*Robinia Pseudacacia inermis*) seldom, if ever, flowers, but is prized by the owners of suburban front gardens, where the short, twiggy growths take up but little room, and do not darken the windows.

The finest of all the series of hybrids between *Magnolia conspicua* and *M. obovata* is *M. Lennei*, the petals of which are of a beautiful rose-purple

Scotch Laburnums. Neither of the two have so gracefully arching branches as the Common Laburnum, but the latter is often spoiled by pruning and lopping in confined situations, so that its natural beauty in those cases cannot be seen. Laburnums produce a wealth of spurs that bloom year after year if left unpruned.

The Cotoneasters vary much in habit, so that it is well to select positions for each, where it can assume its natural habit of growth. *C. horizontalis* is often planted against a wall, but nowhere does it look more natural than in an open situation, such as a circular bed on the grass. The branches grow out horizontally in all directions a little way above the soil, and sometimes a strong branch will rise higher and then spread out again, forming a higher table of densely leafy branches.

THE SNOWY MESPILUS BACKED BY EVERGREENS.

The berries hang on for many weeks after the leaves have mostly dropped.

A relation of the Horse Chestnut, namely, *Xanthoceras sorbifolia* has leaves somewhat resembling a Mountain Ash, and a profusion of white flowers. Unfortunately, these sometimes get injured by late frost. It flowers with more certainty when trained upon a sunny wall, and is an excellent plant for forcing in pots. The fruits are like the Horse Chestnut without the prickles.

The handsome *Prunus triloba* does not appear to be known in the single state, for the pale rose flowers are double, and though the young fruits appear to set, they soon fall away. The small tree is really an Apricot. It may be grown in a variety of ways, and is effective as a group in a large bed, where it may be kept dwarf by pruning it hard after it has done flowering. It will cover a wall 10 ft. high, and if the side shoots are hard cut back after flowering a succession of flowers in the greatest profusion may be had every year. It is also an excellent plant for forcing.

Of exceptional beauty are the Birches, with their graceful branches and peculiar trunks. These trees deserve to be planted to a greater extent than they are to-day. The silvery trunks of some species are a notable feature of the garden during the winter months.

Our native Birch (*Betula verrucosa*) is exceptionally beautiful. Some species have darker and more rugged trunks than others, but, nevertheless, they have a charm which is quite their own.

The Birches are deciduous and bear unisexual flowers, which are produced on catkins. Male and female catkins are borne on the same tree. They are formed in autumn but do not expand until the spring; therefore the Birches are never without some attraction. Many of the species are aromatic, which greatly enhances their value.

planting to choose a position where its flowers will show to the best advantage, against a background such as the evergreen Oak or Holly would provide. If planted in association with early-flowering shrubs, such as Almonds and double Cherries, the effect produced is extremely pleasing. The Snowy Mespilus is closely related to the common Medlar (*Mespilus germanica*), but the flowers of the former are smaller. The Snowy Mespilus is one of the daintiest and most profusely-flowered trees of spring.

It is not at all fastidious as regards soil and, in common with Thorns and the Bird Cherry may be found flourishing in our sandy woods. As it succeeds in all parts of the British Isles there can be no doubt as to its hardiness.

Cratægo-Mespilus Asnièresii is a small tree with pendulous branches which is deciduous. The name *Cratægo-Mespilus* according to Beau-

Pyrus Malus floribunda (Japanese Crab) is one of the most beautiful of all the flowering Crabs cultivated in gardens. The pale pink flowers are borne in great profusion from the end of April until about the middle of May. The trees average in height from 10 ft. to 15 ft., and as much or more in diameter. The variety *atrosanguinea* is much richer in colour and the two trees grouped together form a glorious floral picture. As a specimen plant for lawns, *Pyrus floribunda* is to be highly recommended both for large and small gardens.

The Snowy Mespilus (*Amelanchier canadensis*) is, when it is in bloom, so smothered with the profusion of its pure white flowers as to resemble a huge snowdrift in the distant effect. Flowering, as it does, during early spring, it is advisable when

"has been devised to distinguish three deciduous trees, one a supposed natural hybrid between the Hawthorn (*Cratægus monogyna*) and the Medlar (*Mespilus germanica*), the other two hybrids obtained by grafting the Medlar on the Hawthorn."

Cratægo-Mespilus Asnièresii in habit resembles a large-flowered *Cratægus* of semi-pendulous growth. A few spines are noticeable, and there are two kinds of leaves, some entire and the remainder deeply lobed, especially those on the vigorous young shoots showing the Hawthorn parentage. The leaves on both surfaces are very downy. The flowers are produced in clusters like those of the Hawthorn, but are larger, averaging 3 in. across, six to twelve, sometimes more, in a corymb, white, tinted rose with age. The fruit is brown in colour, oblong in shape and about the size of the Hawthorn. The flowering season is the latter half of May. This is a most desirable tree for gardens.

There are many beautiful trees which thrive under smoky conditions. It is best to plant deciduous trees as these shed a great quantity of the dirt with their leaves in autumn.

Fortunately there are some evergreens that stand these conditions fairly well. *Ilex Aquifolium* (the common Holly), and its glossy-leaved forms, is one of the best evergreens for a smoky district. The *Aucuba* gives quite good results in several places. *Berberis stenophylla* stands well under these conditions. *Berberis Aquifolium* and *Box* are also excellent plants. The common Ivy seems to flourish under the most unsatisfactory conditions, while its numerous tree forms also give good account of themselves.

Among deciduous trees the Plane undoubtedly has become famous for resisting the enervating effects of London smoke. The red-flowered Horse Chestnut grows very well under unsatisfactory atmospheric conditions; the same applies to the Ash. Among the *Pyruses* may be mentioned *P.P. floribunda spectabilis* and *Ringo*.

This by no means exhausts the list of desirable trees for gardens either large or small, but it should suffice to show the reader what a vast collection there is to choose from.

A BEAUTIFUL HYBRID: CRATÆGO-MESPILUS ASNIÈRESII.

SUMMER BEDDING PLANTS AND PLANTS FOR VASES AND BOXES

DURING the past eight years or so the stocks of bedding-out plants, generally used in the flower garden from June till October, have been in many cases almost entirely depleted. Numbers of them are again finding favour with cultivators, but where stocks are quite insufficient plants should be bought or supplemented by charming annuals.

Old plants of Zonal Pelargoniums, Fuchsias and Heliotropes should not be thrown away as by their judicious use a very charming display may be obtained at a small cost, as regards labour, in the flower garden. For a period of ten years I used the same old specimens—nearly one thousand of them—in a large garden with great effect. During the winter months these veterans were stored in gin and roin pots in Peach houses and vinerias from which frost only was excluded. In the spring new shoots grew freely but not strongly, and in consequence, flowered profusely in the summer. The specimens varied in height from 1ft. to 4ft. and were employed to form pyramids of not too formal shape. They entirely filled some small beds and looked very well with shrubberies as a background. The tallest plants were made secure to strong central stakes, the latter being hidden from view by the foliage, and the remainder, according to height, were then planted to form the pyramid.

Of course, each kind was kept separate and not mixed in the beds. The edgings to such beds may be of any dwarf-growing plant favoured by the cultivator. The majority of the beds referred to were edged with Echeverias planted face outwards in a ridge of wet soil and cow-mannure, mixed. When the mixture dried it retained its shape throughout the summer.

PLANTS FOR VASES AND BOXES.—The various plants required for these receptacles should be selected now and placed by themselves, not unduly crowded, so that they will be extra sturdy to withstand strong winds and show to the best advantage. The vases of pottery must not be painted, but tubs and boxes should be painted dark green or oak colour. Whether placed directly in front of a dwelling house or in odd positions, such as recesses between clumps of shrubs, beside the paths or on the open lawn they have a charming effect when properly filled. For the garden vase, one of the most satisfactory forms is the top section of the ordinary Italian oil jar. The jar ought to be cut a trifle below the bulge, as shown in an accompanying illustration.

There are two kinds of plants very suitable for planting in vases, namely, Fuchsias and Ivy-leaved

Pelargoniums. The former grow erect but gracefully, the latter, depending from the edges, are also very effective. The colours of the flowers should harmonise.

PLANTS RAISED FROM SEEDS SOWN IN SPRING.—Lobelias, Pyrethrums (Golden Feather), Petunias, Pansies, Marigolds, Tagetes, Nasturtiums, etc., must be transplanted in boxes, in beds, in cold frames or in temporary shelters prior to full exposure and final planting.

POTTING ZONAL PELARGONIUMS SINGLY.—As the plants are not placed in the flower garden before the first week in June there is ample time for them to get well rooted in small pots before that date, and specimens so treated are more easily

fairly large pots the latter may be buried in the soil without turning out the plants, just covering the rims with soil; from small pots the Liliiums may be planted out carefully.

CALCEOLARIAS.—Frequently many of these plants die soon after they are planted in the flower garden. I have found the cause to be, mainly, too late planting in the hot weather and burying the stems too deeply. Where it is convenient the Calceolarias should be planted in their summer quarters early in May. GEORGE GARNER.

DO NOT "DRAW" THE CHRYSANTHEMUM

Undue "coddling" is inimical.

I PARESAY many cultivators have noticed, late in the summer-time, plants with rather thin stems near the base and much thicker higher up. This is caused, mainly, through pampering the young plants—being too kind to them in their early stages of growth, thus unduly drawing up the stems under glass late in spring.

All late-flowering plants, propagated before, or soon after, Christmas, have to remain under glass longer than the others, so extra care should be taken with them. The majority of such plants are stopped late in March or during April, and, if their stems are weakly at this stage, the shoots following the stopping will be weakly, too, and time is much too valuable to be lost in this way.

To avoid having weakly plants place them in cold frames as soon as possible after they are established in the small pots. Rather than retain the plants in the warm greenhouse in a mild spring, or late winter-time, I transfer them to the cold frame in the month of February. Place the pots on a bed of ashes in preference to boards. For a number of years I sifted the ashes and used the fine ones on the top, but earth-worms entered the pots. Now, I still sift the ashes, but place the coarser ones on the top. This prevents the worms rising high enough to gain access to the pots.

Allow ample room for the plants to grow—overcrowding would cause weakly growth even in a cold frame. Close the glass lights for two days or so after placing the plants in the frame, afterwards ventilate freely except in bad weather. Put on some covering material at night if there is a frosty air.

The following varieties should receive special attention in this way: A. F. Tofield, Edith Cavell, General Petain, Louisa Lockett, Mrs. Algernon Davis, Mrs. G. Drabble, Mrs. M. Sargeant, Mrs. R. C. Pulling, Miss A. E. Roope, Peace, Princess Mary, Queen Mary, Shirley Golden, Victory and W. Rigby. G.

AN ITALIAN OIL JAR RIGHTLY PLACED.

transplanted and thrive better than those planted direct from the cutting pots or boxes. Of course, cuttings of these plants rooted in spring may be taken direct from the cutting pots to the flower garden.

TUBEROUS BEGONIAS AND LILIUMS.—Where the first named are grown in large numbers they are mostly retained in boxes, but by far the best plan is to place them in pots and to re-pot in due course if they are in small pots and becoming pot-bound. Too much shading should be avoided at every stage or else the leaves will be scorched when fully exposed to the sun. If the Liliiums are in

THE LONDON DAFFODIL SHOW

ACCORDING to the R.H.S. arrangements it should have been Daffodil Day at Vincent Square on April 11, but while societies may propose, the weather certainly disposes in such matters. The cold winds and general backwardness of the season made it one of the smallest Daffodil Shows that the Society has held. It was only the earliest and most favoured gardens that had any show blooms, but while the Daffodils were relatively few in number and mostly from Cornwall, and Waterford, Ireland, they were all of outstanding merit. The present-day show flower possesses a greatly increased substance which makes it a "better traveller" that lasts much longer when cut than is the case with its forbears, and also the purity of its colours is also greatly improved. Such flowers were to be seen in sufficient numbers for admiration, even though the competitive exhibits were few.

The chief prize-taker was Mr. J. L. Richardson of Waterford. He had no competitor in Classes 1 and 2, which are for thirty-six and eighteen representative varieties, and he was awarded the first prizes for really good collections. He showed a number of unnamed seedlings, and also Sirdar, Red Lady and Victory among the named sorts.

In the new seedling classes the Donard Nursery Company, Newcastle, Co. Down, won the Engleheart Challenge Cup with twelve varieties not in commerce, and the silver-gilt Flora medal with twelve seedlings introduced since 1914. One cannot enthuse over the cup collection, as, although good blooms, they were unnamed, but the other

THE NEW NARCISSUS "SILVER CHIMES." (AWARD OF MERIT).

exhibit was strong in the Trumpet section, of which Comely, Gog and Magog and that most useful of all large sorts, King Alfred, were very good.

Non-competitive exhibits were set up by several trade growers. In spite of the difficulties of the season, Messrs. Barr and Sons had a wonderful display for which they were awarded a gold medal. The exhibit included perfect blooms of all possible sections. Such large Trumpet varieties as Fantin Latour, Mustapha and Latona were equal to any in the Show. These are, of course, rather high-priced novelties, but there were plenty of all types at every-day prices. Ornement, a glorious Barri variety, is one of these, and so are Jaime à Merveille and Rembrandt, two useful Poetaz sorts.

Double Daffodils were in every collection, and Barr's had splendid blooms of Primrose Phoenix, which is perhaps, the best of them all. Irene Copeland, a large, shapely flower of paper white and primrose colour, and Copeland's Seedling were in the Donard Nursery group. The most distinct of the new doubles was Mrs. E. Martin, shown by Mr. J. C. Martin. This is said to be a cross between Gerrard's old Lent Lily and a Poeteus variety. It is somewhat like a thinly arranged Gardenia Daffodil enclosing short salmon petals. Gullrock on the same stand is a pale lemon and primrose double.

Phantasy (a pale cream Trumpet), Empire (a giant Leedsii) and Brilliancy (an Incomparabilis with a vivid corona) were very prominent in an exhibit by Messrs. Cartwright and Goodwin. Torch and Carnival are two others of brilliant coronas which were to be seen in several exhibits. Messrs. F. H. Chapman, Limited, had some choice

seedlings, but these, like Mr. Engleheart's giant Maximus varieties, were shown under seedling numbers. The decorative value of various Daffodils was illustrated by the Anglesey Bull Growers' Association, who massed various sorts in brown wicker-covered jars and vases.

Of the general exhibits the greatest interest seemed to be centred in Sutton's coloured Freesias. Not only were these in many new shades of colour, but were exceptionally fragrant for the type. Generally these new Freesias fail in this respect, but if grown in the cool greenhouse many are quite pleasantly perfumed. Mosette is perhaps, the best of all in this respect. For uncommon colouring the rose pink edged and yellow flushed La Charmante was most fascinating. Apogée is of perfect form, and the deep Golden Canary is also delightful.

Pleasing fragrance was also present in the large batch of Iris punila formosa shown by Messrs. G. G. Whitelegg and Co. These plants, although quite hardy, might also be grown in pots in the cool greenhouse for early spring display.

Late-keeping Apples, so good as to win a silver Hogg medal, were shown by Messrs. G. Bunyard and Co. The best of the many sorts were Mother, Easter Orange, Allen's Everlasting, Mannington Pearmain, Cabalva and Hensgen's Golden Reinette.

The Narcissus Committee also concerns itself with Tulips, and, although there were no awards given to novelties, there were several collections of exceptional interest. For some little time past Messrs. R. H. Bath, Limited, have shown how well Darwin Tulips can be grown in pots and little

THE WELL KNOWN DAFFODIL KING ALFRED.
One of the best for massing.

NARCISSUS ORNAMENT.
Soft primrose and fiery scarlet.

jariniere of fibre, and on the present occasion they really surpassed themselves. The flowers were all of "first size," perfect in colour and borne on exceptionally long, stout stems. Forced Darwins, especially earlier in the season, have a tantalising habit of coming rather weak in the stem, so that the flowers nod unduly and so lose most of their charm; but there was not the slightest suspicion of this with Messrs. Bath's collection, nor with the decorative group by Messrs. Carter and Co.

Of the great variety of Darwin Tulips it was perhaps the vivid, glowing colour of Petrus Hondius that most held the eye and compelled admiration, although the soft pink colour of Clara Butt, which is lightly tinged with salmon, also had many admirers. King Harold, rich dark blood red; Baronne de la Tonnaye, bright rose with silvery edging; Bartignon, carmine crimson; Euterpe, brilliant clear lilac; and White Queen are also admirable sorts.

The dwarfier, sturdier Dutch Tulips were shown by Messrs. R. and G. Cuthbert, who had splendid blooms.

At one time the National Rose Society had intended holding their Spring Rose Show on the present occasion, but for various, and no doubt good, reasons decided to postpone it for ten days or so and go to the London Scottish Drill Hall. Judging from the several exhibits of forced Roses at the R.H.S. Hall, it is a splendid season for forced blooms, and besides the quantities of the new *Souvenir de Claudius Pernet*, Mr. Walter Easlea had lovely blooms of *Columbia* and *Premier*, among many others. Mr. George Prince again showed graceful sprays of the *Yellow Banksian*; but these were quite overshadowed by the brilliance of *Padre*, which is one of the new Roses of last year. Among the many sorts so finely set up by Mr. Elisha J. Hicks there were several

fine vases of the fragrant soft pink *Mrs. Elisha Hicks*.

Sometimes one is almost inclined to think there should be a short close season for the greenhouse Carnations, but it would be a difficult matter to say when that interim should be. All through the winter these Carnations are indispensable, and now that other flowers are becoming more plentiful, such magnificent Carnations as those shown by Messrs. Allwood Brothers, Mr. C. Englemann, Messrs. K. Luxford and Co. and Messrs. Stuart Low and Co. forbid any suggestion that the present should be a close season. When it was first shown some had their doubts as to the lasting qualities of the glorious scarlet *Edward Allwood*, but it has proved almost equal in this respect to the beautiful pink *Lady Northcliffe*, which is well known as one which outlasts all others when out.

NEW AND RARE PLANTS.

Narcissus Golden Pedestal.—A golden yellow companion to *White Pedestal*. It may be termed a glorified *Sir Watkin*, possessing perfect form, plenty of substance and a deeper coloured corona. A really beautiful flower which should have a great future. Award of

merit to Mr. J. L. Richardson.

Narcissus Magog.—An immense Trumpet even larger than *King Alfred*, which it closely resembles. The only other difference appeared to be not so rich a golden colour and a rather more open tube. But it is a very showy flower. Award of merit to the Douard Nursery Company.

Narcissus Silver Chimes.—This is an exceptionally beautiful *Tazetta-Triandrus* Daffodil. It produces a beautifully clean stem bearing five or six dainty blooms. The perianth is white and the long cup is primrose coloured. It should be a valuable sort for garden display as well as for exhibition. Award of merit to Mr. J. C. Martin.

Narcissus White Nile.—A medium-sized Trumpet Daffodil of ruffled appearance. The perianth is white and the long trumpet, which is prettily frilled, is lemon yellow in colour. Award of merit to Messrs. F. H. Chapman, Limited.

Freesia Mouette.—One of the many beautiful coloured *Freesias* in the Reading exhibit and quite the most fragrant of them all. It is a good spike of large, widely expanded blooms delicately flushed on cream ground with lilac and brightened

NARCISSUS GOLDEN PEDESTAL (AWARD OF MERIT).

NARCISSUS JAUNE A MERVEILLE

by a little orange colour on the lower petal. Shown by Messrs. Sutton and Sons.

Rose Souvenir Claudius Pernet.—A large vase of this handsome *Pernetiana* variety was shown. Even when forced it has long, stout stems and dark green foliage. The blooms are of good shape until just after full bloom, when they spread rather much. The centres are of deep yellow colour and the outer petals are bleached somewhat in the *Sunburst* manner. It seems a splendid Rose for forcing. Award of merit to Mr. W. Easlea.

Bougainvillea Mrs. Butt.—This most brilliantly beautiful *Bougainvillea* has long been grown in Jamaica and other West Indian Islands, but is quite new to English gardeners. A small plant was shown, but it apparently had been subjected to a rather too high a temperature, as the flowers wilted quickly. But it can be grown as readily in a warm greenhouse as the well known *B. glabra*, when the flowers last quite well. The colour is rather variable, but may be described as being reddish crimson. Award of merit to Messrs. Stuart Low and Co.

Cymbidium Castor var. Claytoniensis.—A handsome, robust, arched spike bearing a large number of well formed blooms. The sepals and petals are of old ivory colour flushed and lined with rose, and there are rosy carmine lines on the lip. Award of merit to the Rev. J. Crombleholme.

Odontoglossum eximium Mabel.—A well marked flower of good substance. It is of velvety chocolate maroon colour with definite white margins. Award of merit to Pantia Ralli, Esq.

Oncidioda Stuart Low.—This strikingly beautiful Orchid has long trails of almost butterfly-like flowers of reddish maroon colour occasionally flushed with orange. The curious projecting lip is tipped with golden yellow. Award of merit to Messrs. Stuart Low and Co.

CORRESPONDENCE

ROTATION OF CROPS.

IT is the general opinion that crops always do better with a change of soil and the land will be cleaner and healthier for it. A good gardener will work and cultivate his land in a thorough manner, using large quantities of organic manure, and invariably plant it with any seasonable crop that he has handy. In doing this he may not adhere to the rotation system, though the results prove satisfactory. Many reasons are given why crops should be grown in rotation. At one time botanists thought that the roots of plants gave off some kind of excrement which poisoned the soil and made it unfit for the same kind of crop again. Another plausible explanation was that by continually growing the same crop on the land it became impoverished and unable to produce a good or paying crop. Practice has proved that all the ingredients which form the plant food can be replaced without any appreciable loss. It should be remembered that plant food is taken up by the roots in the form of nitrates; also plants require nitrate, potash and phosphates to bring them to perfection. One of the best reasons for rotation is the prevention of indigenous diseases. It is quite common to hear the remark "My Cabbages always club on that patch of garden," although the remedy is easy. Supposing a crop of Cabbages is attacked by the club (*Plasmiodiophora brassicæ*), the spores will remain in the ground in a resting or dormant state. Cabbages are planted on the ground. After the resting stage the spore bursts and releases the slimy fungus, which is distributed by the first downfall of rain. In this way it comes into contact with the young rootlets of the Cabbage plants, which absorb the fungus, and the plants are again attacked with club to the disgust of the grower. A crop of Peas, Beans or Potatoes would have prevented this. The same thing applies to the Potato crops and the Potato disease.—R. D.

A LITTLE KNOWN ROCK PLANT.

A PRETTY mass of *Draba Athoa* was a conspicuous though modest feature in the rock garden of the Royal Botanic Gardens, Edinburgh, in the first week of April. It is not much cultivated in gardens, and is comparatively little known. A sheet of it in the rock garden was quite bright with its numerous clusters of flowers just a little above the cushions of spiny foliage, the whole creating a bright impression with the golden yellow of the flowers standing out well against the dark rocks of the garden. It belongs to the section called *Aizopsis*, which comprises a number of *Drabas*, almost entirely with yellow flowers, and forming cushions rather than carpets, and with the leaves edged with spiny teeth or bristles. It comes from Greece, where it is limited to the tops of several mountains. It has broader foliage than some of the plants of the same section, and has good-sized flowers with conspicuous anthers. It does not seem difficult to cultivate and looked thoroughly happy at Edinburgh.—S. ARNOTT.

ALPINE PLANTS IN PIG TROUGHS.

A VISIT to the garden of Mrs. Saunders, sen., of Wennington, near Lancaster, revealed to me many of these plants growing with wonderful vigour in small sandstone pig troughs, especially several of the *Primulas*, as *helvetica alba*, *pubescens* and others. *Daphne rupestris*, a grafted plant, but only a little smaller than the one so often shown by the late Mr. Farrer, was in good condition. *Saxifraga Irvingii*, some six or eight clumps (in one trough), each at least 3 ins. across, in full bloom, was very fine; but the

plants that I admired the most were two large clumps of the rare *Saxifraga Boydii*, true, both in full bloom—"A sight for the Gods." I have not seen during my forty years of growing alpine such fine healthy plants and so freely flowering. Mrs. Saunders also had *S. oppositifolia* very fine, as also the white form. This latter struck me as being a clearer white and with larger flowers than usual. These were grown on the borders and were collected by Mrs. Saunders.—T. O. W.

A RARE PRIMULA.

I AM sending a photograph of *Primula Fortunei*, which, I understand, is a very rare plant. It is a Chinese species and somewhat resembles *P. farinosa*. The rosy-lilac flowers are borne on

A CHOICE CHINESE PRIMULA.

larina-covered stems, thus giving this plant an extremely graceful appearance. Unfortunately, *P. Fortunei* is not quite hardy, and during cold weather is best given some protection. If grown in a pot or pan it makes an excellent plant for the alpine house. I cannot find this desirable plant listed in any catalogue that is in my possession, and I should very much like to know if anyone has a stock of it. It would be a great pity if this beautiful *Primula* became extinct.—C. H.

A SELECTION OF SHRUBS.

ANSWERING "H. E." in your issue of April 8 (page 167). I have endeavoured to get together a short list of shrubs, most of which I have both seen and tried on a chalk soil. It is not an easy matter to give a selection of the best shrubs for a chalk soil without knowing the locality and exposure of the garden for which

"H. E." seeks advice. Many of the rarer and more interesting shrubs require the shelter of semi-woodland, or at any rate some "line of defence" from cold northerly and easterly winds, otherwise the soil indicated, "namely, chalk under a good deep soil," would grow almost anything that does not belong to the *Rhododendron*, *Azalea* and other lime-hating families. "H. E." asks for four or five dozen of the leading species. I am wondering if he only intends to plant one variety of each species, and, if so, would beg of him to reconsider this, in that far better effects are obtained by grouping several plants of one variety together. Such groups may vary in size from three or five to a dozen or more plants, and each group should be isolated from its neighbour by an under planting of some dwarfier shrub.

The best evergreens that are not considered flowering shrubs would be *Phillyrea*, of which the species *P. Vilmoriniana*, *P. angustifolia* and *P. latifolia* are perhaps the best. Holly, of which nothing is better than the common hedgerow form. *Juniperus*: *J. communis* and the Spanish Savin, *J. tamariscifolia*, also *J. tripartita* and others. *Elæagnus*: *Vars. glabra*, *macrophylla* and *pungens*. *Laurus nobilis* (Sweet Bay) and Box, with *Castanopsis chrysophylla*. A generous grouping of all or any of these would give the necessary background and shelter and help to modify the otherwise bare effect that many deciduous shrubs give in the winter months. One might add the Golden Yew, *Retinospora squarrosa* and *Cryptomeria elegans* for winter colour, and the double-flowering Gorse. For flowering shrubs I will begin the year with *Chimonanthus fragrans*, the Japanese Allspice; *Berberis Bealei*, the winter-flowering variety of which is, I believe, now catalogued as *Berberis japonica hyemalis*; *Berberis intermedia*, similar to the foregoing but having rather larger darker green leaves and flowering a little later; *Azara microphylla*, with small dark evergreen leaves of vanilla scented but otherwise inconspicuous flowers. I also like *Ruscus aculeatus*, the Butcher's Broom, for a shady place under trees. It can be found growing wild both on clay and chalk. *Daphne Laureola*, or Spurge Laurel, being dwarf, is an invaluable shrub for underplanting either in sun or shade, and is especially fine in winter with a further underplanting of Snowdrops. It can often be found growing wild, but as it does not transplant very well small plants only should be used. It would probably grow quite well from seed after a year or possibly two year's germination. *Daphne Dauphina* can also be recommended. *Daphne Mezereum*, both the white and pink varieties, thrive well on chalk, and will often seed themselves, to which the same remarks apply as the foregoing. Established specimens should on no account be pruned or cut to any great extent. I can thoroughly recommend large groups of this *Daphne*, which gives flowers in February and March, and berries later in the year. The pink *Daphne Mezereum* associates well with an underplanting of purple *Crocus*. I here mention a new shrub that was, I think, introduced by Messrs. Smith of Newry, known as *Prunus subhirtella var. autumnalis*. The words "price on application" in Mr. Smith's catalogue need no further explanation. It is a valuable shrub, however, blooming from November to May. Paul's new purple-leaved Peach and *Berberis vulgaris fol. purpureis macrophylla* come to mind as giving good purple colour in their leafage. *Cornus Mas*, the Cornelian Cherry, and *Forsythia suspensa*, together with *F. intermedia spectabilis* and *viridissima*, bring the genera of shrubs already mentioned up to twenty. Here I name *Choisya ternata* or Mexican

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Peas.—Where a regular supply of these must be maintained to well into the autumn a sowing should be made every fortnight or three weeks, according to the supply required. In some districts it will not be of much use to sow later than the latter part of June, but in favourable localities and where the soil is warm and well drained it is possible to sow right up to the end of July or even during the early days of August. For these later sowings the spot should be carefully selected and a quickly maturing variety should be sown for preference. In making sowings for the next few weeks which will furnish the main supply it will be advisable on light soils to sow in a shallow trench, thus affording the roots some shelter from hot sun and also providing a receptacle for possible rains and mulchings. It is important that the early sown Peas are staked as soon as it becomes necessary.

Orange Flower, and *Osmanthus Delavayi*. Among April-flowering shrubs there are so many it is difficult to make an eclectic selection, but I think there are few that can beat the varieties of *Pyrus japonica*, of which *cathayensis* and *Sargentii* are comparatively new and little known, while the old cottage *japonica* is very hard to beat, because few rare and expensive so-called novelties are superior in sheer beauty of flower to this homely wayside shrub. Personally, I have great affection for the April-flowering double *Kerria japonica*, another old-fashioned garden shrub rarely seen now except in old and neglected gardens, and the same may be said of *Leycesteria formosa*. The former is especially fine when trained to grow over a short pergola arch or clambering over a summer-house. Its green stems give quite good winter colour; while *Halesia tetraptera* is a good April and May flowering shrub. Messrs. V. Lemoine of Nancy have a very fine new pink Lilac which is named *Syringa Sweginowii superba* (A.M., R.H.S.). For May nothing can beat the Philadelphia or popularly known *Syringa*, of which the best varieties are *purpurea maculatus*, *Virginal Fantaisie*, *Voie Lactée* and *Mont Blanc*. Among species of Philadelphia, *Yokohama* (*Satsumi*) is perhaps the best. For June *Halesia hispida* and *Styrax obassia*, *Magnolia conspicua* (*Yulan*) and its variety *speciosa*, *M. Soulangeana*, *M. stellata* and *M. parviflora*, *Buddleias*, *Lonicera syringantha*, *Exochorda Giraldii*, *Diospyros Kaki* (*Persimmon*), *Deutzia magnifica*, *Cercis Siliquastrum* or *Judas Tree*, *Fuchsias* (*glabosa*, *Riccartonii*, *gracilis* and *macrostemma*), *Hibiscus* in varieties (*Bleu Celeste* and *alba*), *Cistus crispus* *Sunset*, *Cistus purpureus* and *Helianthemum*, many of the *Cornus* tribe, particularly *C. Kousa* or *Benthamia japonica*, *Viburnum Opulus sterile*, *Viburnum plicatum* (very fine in June and again for autumn colour), *Crataegus Crus-galli* (*splendens*), *Hydrangeas*, *Cotoneasters* in variety, *Erechas* in variety, *Chionanthus* (the *Fringe Tree*), *Aesculus parviflora* (late July), *Ceanothus azureus*, *Ceratostigma Willmottiana* (*Miss Willmott's Plumbago*) for July, August and September; *Caryopteris Mastacanthus* (July and August), *Paliurus aculeatus*, *Ruscus racemosus*, *Berberis* in variety and the lovely autumn colouring of *Parrotia persica*, *Vinca difformis*, *Veronica parviflora hyemalis*, *Hamamelis mollis*, *Rosemary* and *Lavender* must end a somewhat disjointed list of shrubs that have come to mind as being among some of the best. I would like to mention the old-fashioned *Lycium europaeum* (*syn. European Box Thorn*) as growing well on chalk.—EDWARD SHOOSMITH.

A PRETTY ANNUAL FOLIAGE PLANT.

A SOMEWHAT unusual annual not generally grown is *Kochia trichophylla*, commonly known as the *Summer Cypress* owing to its resemblance to a tiny *Cupressus*. This beautiful ornamental annual should be sown in prominent positions either in beds or borders. The plants attain a height of 2ft. to 2½ft., and are a pleasing light green in colour. But the great charm of this plant is revealed when in autumn it matures. It then turns a brilliant crimson. When the colouring takes place the plant is really dying, but fortunately dies slowly! The *Kochia* is exceedingly useful as a dot plant and is also adaptable to pot culture. The plants are egg-shaped or columnar. It is a relative of *Kochia scoparia*, which is a terrible weed in some gardens. If grown in pots it makes an excellent plant for the dwelling-house, especially if placed in a prominent position in the hall or on balconies. Seed may be sown now where the plants are to flower, but drastic thinning must be resorted to when the seedlings appear.—L. H.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Early Cauliflowers.—Plants raised under glass should now be sufficiently hardened off for planting in the open. Plant on a warm part of the early border which has been deeply dug and thoroughly enriched during the autumn or winter months. Fork over and plant in rows 18ins. apart. For dwarf-growing sorts, such as *Dean's Snowball*, 1ft. apart in the row is enough. Dust round the plants with soot or lime to protect from slugs.

Early Sowings of Beet.—A sowing of Egyptian Turnip-rooted or *Sutton's Globe Beet* may now be risked. Choose a part of the garden that has not been subjected to recent manuring. Beet may readily follow Brassicas or Peas as a rotation, and give excellent results. Sow thinly in drills 15ins. apart and thin out the young plants to 9ins. apart in the row.

Vegetable Marrows.—Sow seed for the main crop in small pots and germinate in a warm greenhouse. As soon as the young plants develop their tough leaves they should be potted on into 6in. pots and grown on in a genial temperature, gradually hardening off for planting out at the end of May. Even at that date they must be sheltered at nights, as young Marrow plants are readily susceptible to the least touch of late frost or the influence of biting winds. *Rotherside Orange* has proved a fine variety, the fruit being of convenient size and of excellent flavour.

Lettuce.—Plants that have been raised under glass may now be safely transferred to quarters in the open. Make fortnightly sowings of *Cos* and *Cabbage* varieties.

Tomatoes.—The earliest batch in pots will now be requiring some assistance in the way of feeding, as the genial influence of sun-heat assists rapid development of the fruit. Where several trusses are well set occasional waterings with liquid manure may be given. Attend to the tying of successional lots and remove all lateral growths as they appear.

Fruit Under Glass.

The Orchard House.—Where a good set of Peaches and Plums has been obtained on pot plants the syringe should now be used freely so that red spider and aphid may be kept in check. Discretion must be used when disbudding, retaining ample growths for next season's fruiting. When the fruits begin to swell a little stimulant may be afforded. Ventilate freely during fine weather.

The Shrubbery.

Transplanting Evergreens.—This period is favoured by many for the planting of evergreen shrubs, and there is no doubt that if the work is carried through in suitable weather the plants make a quick recovery at this time. In moving specimens have the site prepared and do not expose the ball unnecessarily to the weather, as drying winds shrivel the fibrous roots. Should dry weather prevail give the plants a thorough soaking of water to settle the soil about the roots. Hollies may be moved with safety from now till the first week in May.

Forsythia Fortunei.—This variety with us is the earliest flowering of all the *Forsythias*, having now been in bloom for several weeks. It should be pruned immediately it is past flowering so that plenty of young wood may be produced for next season's display. Where it is trained to a wall or fence do not tie in too closely. Make firm the main branches, but leave the light, pendulous shoots free. This attention adds considerably to the plants' attractiveness when flowering.

Cutting Ivy on Walls.—Ivy on walls requiring trimming should be attended to now. Cut closely and take out any thick, coarse growths where possible. Always aim to have a thin sheet of fresh growth, as nothing looks worse on a wall than lumpy and irregular Ivy. Where this condition prevails it is better to cut right back to the ground and let the plants come away afresh.

The Flower Garden.

Preparing Flower-Beds.—All beds which are bare of spring-flowering plants should now be dug and put in order for summer bedding. If manure is added see that it is well decayed. Fresh manure too readily causes over-luxuriant foliage with corresponding scarcity of flower.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

The Flower Garden.

Pentstemons.—The planting of these should be completed without delay so that the plants may get well established before the hot weather sets in. The best effect is obtained when whole beds or borders are given up to them and the massing of the plants is carried out in a properly thought out colour arrangement. They will repay a good soil prepared for them, and at a later date, when the spikes are developing, a mulch of well rotted manure and leaf-soil should be given in equal amounts.

Stocks.—The hardiness of the East Lothian Stock makes this valuable strain almost indispensable where this family of plants is appreciated. Late autumn sown or those raised early this year should now be placed in their flowering positions, being careful not to damage the roots, as Stocks frequently resent removal. This Stock makes an excellent groundwork for such plants as tall *Gladioli*, some of the *Liliums* and standard *Heliotropes*, according to colour.

The Hardy Fruit Garden.

Mulching.—On light soils this is a most important operation, and may almost be termed a necessity to newly planted trees against walls and buildings if the required amount of moisture is to be preserved for the roots during the hot weather. Trees in the open do not, of course, suffer nearly to the same extent, but where the material may be had a mulching is undoubtedly helpful on light, porous soils. Failing a sufficiency of decayed manure, a most suitable one may be made by adding some decaying leaves and lawn mowings to as much of the former as is available. Trees carrying stone fruits probably show ill-effects from lack of moisture the most, so should receive attention first.

NOTE.—When the fruit is setting after the Blossom has fallen, give apple and fruit tree one or two light sprayings with a teaspoonful of Paris-green (Poison) kept well mixed in 4 gallons of soapy water. Sure death to caterpillars; also prevents fruit becoming maggoty. 4 gallons enough for about 24 trees.

THE GARDEN

No. 2632.—VOL. LXXXVI.]

[APRIL 29, 1922.]

PLANTS FOR THE WATERSIDE

THE treatment of the margins of water in the garden requires very considerable forethought if summertime is to prove a complete success. How refreshing and restful it is on hot, parching days when all Nature is thirsty to happen upon a well planned and furnished piece of water where one

may stroll right down to its edge and in the welcome, cooler shadow of some fine tree recline and listen to the drowsy lapping of the current of the stream against the bank, or, better still, if it can be arranged, the musical tinkle of the descending drops of a miniature waterfall. In the greater number of cases, however, it is the

quite small or moderate sized pond, artificially created, that has to be dealt with, and the arrangement of our plants will naturally follow the character of the pond or stream. If this is formal, more or less formality should obtain in the disposition of the groupings; if irregular in shape, Nature herself provides sufficient hints for our guidance.

EFFECTIVE PLANTING AROUND A SMALL POOL.

Overcrowding of the banks, especially with tall-growing plants, should in any case be avoided. Such banks are not herbaceous borders and ought not to look like them. Definite separation and breaking into groups is far more essential round water than anywhere else in the garden. The value of the surroundings should be employed to the utmost, for by skilful arrangement of bog-loving species the apparent size of the whole can be greatly magnified. Whatever plants are employed, use them in groups big enough to be effective and in variety sufficient to maintain the interest. It is unwise to overcrowd, however, for the sake of including a larger number of varieties. Much of the success of a good garden lies in knowing what to eliminate. However small the area of the water, do not completely surround it with tall plants so that it comes on one as a complete surprise. From one part of the garden, at least, it should open out so as to provide a vista. The best bank arrangement of all, where it can be managed, is where the ground rises gradually away from the water on three sides and on the fourth is almost level with the surface, as it can thus by judicious planting be made to appear as though the water had collected in a natural hollow, and yet on the fourth side can be approached near enough to appreciate all its beauties in detail.

The smaller the pond the greater the number of dwarf growers that should be selected to surround it, with only a few outstanding plants to add character and dignity to the whole, always being sure to place those that love the damper soil or to have their "feet in water" nearest to the edge, with others needing less moisture further away, until the ordinary run of herbaceous plants or shrubs is reached. Large foliaged plants are grand where space permits of their full development, especially where they can overhang the water, and of these *Acanthus candelabrum* with its unique glossy foliage, 2ft. or 3ft. long, is splendid, rapidly forming very handsome specimens. A gigantic plant with immense imposing foliage, showing to great effect on islands or where space is quite unrestricted, is to hand in *Gunnera manicata*. It throws up correspondingly large heads of flower in June and July, often 8ft. across and greenish in colour. It comes to us from Brazil, so is safer if a heap of leaves or ashes are piled over the crown in winter as a protection against the severest frost. *Arundo conspicua* is a grand member of the Grass family with dense tufts of narrow, arching foliage flowering in August; while for a position further away from the margin where the ground is not too moist *Arundo Donax*, the giant Reed, is superb. *Heraclium giganteum* is somewhat coarse and useful only where abundance of space can be given it, as it easily attains a stature of 8ft. to 10ft. with large leaves and enormous flower-heads like a giant Cow Parsley. Specially effective is an American plant, *Jussiaea longifolia*, which reaches 4ft. to 5ft. with yellow flowers like those of the Evening Primrose, very freely produced. The willow-like foliage, however, is its chief attraction, especially in autumn, when it becomes deep crimson. Splendid golden sunlight effects on dull days are obtained with *Phragmites communis aurea*, a fine golden variety of the common Water Reed, easily attaining a height of 5ft. The Bullrush is always popular, and even where it does not flower, the distinctive foliage is sufficiently good to ensure its admission. Perfectly hardy in the South, but better for slight protection further North, is *Phormium tenax*, one of the noblest waterside growers. It should have the fullest sunshine, where the enormous sword-like, oppositely arranged leaves develop to their fullest capacity. *Senecios*, particularly *S. Wilson* with

INFORMAL PLANTING ROUND A FORMAL TANK.

THE STEPPING STONES.

its spikes of fine yellow flowers and shiny green leaves look especially striking and handsome close to the water. Bamboos and the strong growing Grasses, such as *Erianthus Ravennae* with bronzy-purple foliage and plumes resembling the Pampas Grass—yet another fine waterside plant—afford a further selection of bold, tall growers should additional plants be required, though these should not be employed to the exclusion of the many beautiful shrubs and small trees available. Rhododendrons and hardy Azaleas merit special mention for the mass of vivid colour they give in May and June and the reflection of these masses thrown back by the calm water surface.

Among dwarf plants suitable for small streams and ponds the number of species is much greater. *Caltha leptosepala* is an uncommon variety of the Marsh Marigold flowering in May and June, the flowers being pure white. The Marsh Marigold itself *Caltha palustris* has several desirable forms, including the double variety, *monstrosa plena*. Hardy Cypripediums as represented by *C. pubescens* with its golden yellow flowers and *C. spectabile* with its pure white petals and sepals and large brilliant pink pouch are two very choice things worthy of a special position and succeeding best where a bed of spongy peat can be arranged for them, to be always damp, but not sodden. Several Ferns, such as *Onoclea sensibilis* with its light green, slightly glaucous fronds and creeping rhizomes; *Osmunda interrupta*, which flourishes in full sun, with lovely velvety green fronds and fine, vigorous spikes of inflorescence; *Osmunda regalis*, the Royal Fern, with pale green fronds growing to a gigantic size in peaty bogland. All varieties of the Hart's Tongue, *Scelopendrium*, are valuable and, where the soil retains moisture enough at all times, do as well in full sun as in shade. The wonderful hardy Pitcher Plants, or Sarracenias, add unusual interest owing to their unique formation, but should be so placed as to permit of close scrutiny. *Helonias bullata* is specially showy with its rosettes of glistening green foliage which takes on the most vivid red and crimson shades in autumn and numerous bright pink flowers on foot high stalks in summer. The Japanese Irises (*Iris Kempferi*) and the variety of our common native yellow Water Flag with variegated foliage are both splendid, while the Siberian Iris with its long, arching grass-like leaves and wonderfully netted foliage is no whit less desirable. The Japanese sorts and also those fine Flags *I. aurea* and *I. ochroleuca* resent too boggy conditions, though they need an abundant water supply. *Lobelia siphilitica* with its leafy green stems and blue flowers accompanied by *L. tulgens* with its bronzy-red leafage and cardinal-red blossoms is very effective.

Among plants of moderate dimensions *Mimulus luteus* literally revels in bog and is a glorious golden-yellow Monkey Flower that, when once established, crops up in the most unlikely places; indeed, it needs keeping severely within bounds. *M. cardinalis* is at once unusual and striking with its bright cardinal-red flowers which are produced in succession for a very long time. Numerous members of the universal *Primula* family are happy near water, *P. rosea*, one of the most brilliant of all, flourishing in peaty soil so

SUITABLE PLANTING FOR THE SURROUND OF A FORMAL POOL.

moist that it trodden on by the foot water oozes to the surface. Its vivid rose-pink flowers are produced in late spring in wonderful profusion. *P. japonica*, the Japanese Primrose, shows a wide range of beautiful colours and where it gets moisture enough reaches 2ft. high, flowering in whorls, tier over tier. *Primula pulverulenta*, somewhat similar, but with mealy stems, is even better. Extraordinarily beautiful is *P. sikkimensis*, a very strong grower with fragrant umbels of drooping yellow flowers. Care should be taken to label this plainly and conspicuously, as the foliage entirely disappears in winter. *Saxifraga peltata*, with its umbrella-like bronze leaves in addition to its own grasses, forms one of the finest backgrounds to the above Primulas that can be found. A very charming plant is *Spigelia marilandica* with its tufts of foliage and erect growing stems of tubular dark red flowers golden on the inside of the tubes. Spiraeas one and all, so far as the herbaceous species are concerned, are *par excellence*

plants for the waterside and afford a sufficient height range to enable us to choose varieties suitable to any sized sheet of water. The Trolliuses are like gigantic Buttercups with the same intense orange and yellow colourings. A good massing of such varieties as *T. hybridus*, Orange Globe, Prince of Orange and Yellow Globe, in moist loamy soil with a little peat, are a revelation to those who only judge by experience in drier, poorer soils.

One point which should especially be borne in mind when planting near natural water is that those plants which are real moisture-lovers should be kept close to the edge and in such positions that when dry times come in summer the fall in level of the water does not leave them stranded high and dry to fall victims to a roasting sun. Spring is undoubtedly the best season in which to undertake waterside planting as inevitable root-damage is now most quickly repaired. H. W. CANNING-WRIGHT.

FRAGRANT GREENHOUSE PLANTS

In these days of fuel economy it is a puzzle to some gardeners who possess a greenhouse to know how to utilise it to the best advantage under absolutely cool conditions. The following article gives some helpful suggestions and should prove of great value to those who have glass at command.

FRAGRANCE is always a great asset in any plant, therefore many plants, although not possessing large or showy flowers, are universal favourites on account of their delicious and in many cases refreshing perfume. There are quite a number of fragrant plants that can be easily cultivated in any ordinary cool conservatory or greenhouse. They also vary widely in their character, ranging from shrubby and soft-wooded plants to bulbs and annuals. Taking the shrubby or more permanent plants first, we find quite a number with fragrant foliage or flowers. In *Lippia citriodora* (the Lemon-scented Verbena) we have an old-time favourite, the fragrant foliage of which has a peculiarly refreshing quality. True it is hardy at the foot of a warm wall in many parts of the country, still it is always worth growing for the cool greenhouse. It is easily propagated by means of cuttings, and this may be done by introducing a stock plant to a house and securing the young growths as cuttings. *Eucalyptus citriodora* is another plant that should be more generally grown for its fragrant foliage. It is easily raised from seed and soon makes nice plants in small pots.

Quite a number of the Cape Pelargoniums have very fragrant foliage, the best being *P. fragrans* and *P. capitatum* (this species is largely cultivated in the Mediterranean region for the oil which is distilled from its leaves, and which is used as a perfume and also for adulterating otto of roses). Others are *P. crispum* and its varieties, *P. Radula*, *P. denticulatum* and *P. odoratissimum*, while many of the hybrids, such as Pretty Polly, Shottesham Pet, Prince of Orange, Lady Mary and others, have sweet-scented foliage. All the above succeed under the usual cultural methods adopted for ordinary greenhouse Pelargoniums.

Coming to flowering plants, *Daphne odora* is a general favourite, but is not happy for long under pot cultivation, and is best when planted out in a border of light loam with the addition of a little peat. This plant is generally regarded as being difficult to propagate by means of cuttings, but this is really not so, and plants on their own roots are most satisfactory. If grafted on stocks of *D. Mezereum* it usually sheds its leaves, while stocks of the evergreen *D. Laureola* and *D. pontica* usually prove too strong for it. The hardy *D. Genkwa* is worth growing in pans in a cool house.

Luculia gratissima is a beautiful winter-flowering shrub which should be planted out in a border of light soil, as it is never happy under pot cultivation. After flowering it should be pruned hard back, as it produces its flowers at the tips of the current year's growth. This has always been recognised as a difficult plant to propagate, and

even skilled propagators have failed to increase it with any degree of success. One important factor in its successful propagation is that the cuttings must never be allowed to flag, and internodal cuttings generally prove more successful than nodal cuttings.

Buddleia asiatica has a most delicate perfume, and it is surprising that such an old garden plant is not more generally cultivated, as it is particularly graceful with its long, slender sprays of white flowers. It is propagated by means of

Boronia megastigma is a slender, graceful plant. Its small purple-black and dull yellow flowers are by no means showy, but it amply compensates for this by its delicious perfume. For the ordinary cultivator it is by no means an easy plant to propagate and grow successfully, but it is a favourite market plant, being grown in quantity by the few firms who still grow hard-wooded plants for market.

Cytisus fragrans, another market plant, is an old favourite which always attracts on account of its delicate scent. It grows freely in small pots and also makes fine specimens if planted out in a cool conservatory.

There are several greenhouse Rhododendrons which should always find a place in the cool conservatory, especially if they can be planted out, the two best being Lady Alice Fitzwilliam and *R. Forsterianum*, the latter bearing fine large white flowers with a delicious spicy fragrance reminiscent of nutmegs. They are easily propagated by means of cuttings made from half-ripened young shoots.

Osmanthus Delavayi, although hardy in the South, makes a very neat pot plant, its white flowers, which are the largest of all the *Osmanthus*, being produced in great profusion. It is easily propagated by means of cuttings.

Oranges need only a passing mention, as they are so well known. However, they are what are generally known as dirty plants, and require considerable attention to keep them clean, as they are subject to attack from several scale insects. These pests can be kept in check by spraying the plants frequently with a paraffin emulsion.

Primula verticillata and *P. malacoides* both have delicate primrose scent and are easily raised from seed.

Among climbing plants *Lathyrus pubescens*, *Jasminum grandiflorum* and *J. azoricum* should not be forgotten.

Turning to hardy plants used for forcing, we find quite a number commonly used, such as Lilacs and *Wistaria chinensis* and the newer *Viburnum Carlesii*, the flowers of which often get damaged outdoors by spring frosts. Indoors the flowers come pure white, and with the shelter of a cool house may be had in flower at least six weeks before the outdoor plants. Lily of the Valley is so popular and well known that one need only mention it.

Among bulbous plants there are quite a number that may either be forced or brought on slowly in a cool house. *Lilium longiflorum* is, of course, well known. The newer *L. regale*, one of the finest of hardy Lilies, has also proved excellent for pot cultivation and is easily raised from seed, the young plants commencing to flower two years from seed sowing. *L. candidum* can also be used for pot culture, but must be potted during August and grown at all times under perfectly cool conditions. Lilliums, in common with all bulbous

THE FRAGRANT GREENHOUSE SHRUB, LUCULIA GRATISSIMA.

cuttings, which make nice plants for the greenhouse stage in their first year, and if potted on the second year into 8 in. or 10 in. pots make fine large specimens which should be stood outdoors during the summer months, as the flowers are produced during the winter. *Buddleia officinalis*, a later introduction from China, is a stiff-growing shrub without the grace of the former plant. It produces its lilac-coloured flowers during the winter, which are strongly honey scented, very different in quality from the delicate perfume of *B. asiatica*. Nevertheless, many seem to enjoy its more heady fragrance.

Michelia fuscata, more generally known as *Magnolia fuscata*, has small dull purple flowers which are strongly fragrant, one or two flowers being sufficient to perfume a large house.

plants, should be well rooted before there is any attempt to bring them on indoors. Hyacinths may be had in flower over a long period. Roman Hyacinths can easily be had in flower for Christmas; so can Paper White Narcissus, followed later by the Polyanthus and Poetaz Narcissi, also Jonquils and Poeticus ornatus, the latter always popular about Easter. Two Tulips that are distinctly sweet-scented are the double rose-coloured

THE ESPECIALLY FRAGRANT LILAC FREESIA MOUETTE.
Of fragrant plants none is more welcome than the Freesia.

THE EXQUISITELY FRAGRANT LILIUM REGALE.

Murillo and the single Prince of Austria. Freesias can be flowered in the autumn from seed sown during March, but are more generally grown from corms, which should be potted up not later than the end of August or the beginning of September, growing them quite cool at all times. Carnations and Roses should not be overlooked.

Mignonette and Stocks should be used. These are, of course, raised from seed and both require careful cultivation. Although usually treated as an annual, plants of Mignonette by careful cultivation may be kept for several years.

The foregoing does not, of course, by any means exhaust the list of sweet-scented plants that may be grown for the conservatory. Perhaps readers may be induced to write about other sweet-scented plants that space forbids me to mention

J. CURTIS.

SOME FLOWERS THAT IGNORE THE LATE SPRING

THERE are some compensations even in a late and unkindly spring, and one of them is that while so many early flowers are retarded one is able to appreciate to a fuller extent than is usually possible—for a busy man, at any rate—the few which are bold enough to bloom before the "rush" comes. One of these is *Synthyris reniformis*, a hardy Rocky Mountain plant which delights in a cool, semi-shady corner where it will make a glossy green bunch of prettily toothed leaves, above which rise to quins. or so a cluster of flower spikes, each crowded with little blossoms in a very pleasing shade of cool lavender blue. Once happily established *S. reniformis* seems to carry on indefinitely without attention and often rewards us with a second blooming in autumn.

Morisia hypogaea, one of the most charming rock garden plants of any season, is another that seldom fails us, be the season what it may. It believes in following the almanack, and no sooner have we passed the Vernal Equinox than the curious dark green mound of leaves begins to get studded with yellow buds which, within a week of tolerable weather, break into the large, bright yellow, cruciform flowers of which a succession is maintained until we are nearly into summer. A very well drained and sunny position is what this cheerful little Sardinian seems to enjoy, and there, in this garden at any rate, it will bring up a small family of seedlings on its own account if the summer is to its liking.

The common *Muscari botryoides* (Grape Hyacinth) is also faithful to its appointed time, and one can hardly overlook it, for where it enjoys its home it will thrive redundantly enough to qualify for a nuisance list. But the beauty of its blue globes, with their tiny white teeth, and especially the delightful sky-blue shade of the variety *pallidum*, cover many sins, if it has any, and "robustiousness" is, after all, sometimes a rather desirable feature.

In the rock garden, and well out of the way of the ramping and splendid *Aubrietias*, so over-whelming to all else in the abundance of their gorgeous purples, crimsons, pinks, violets and mauves, *Arabis Sundermanni*, with foliage of a pale green and clear rose-coloured flowers, is making worthy efforts, always coming into bloom just before the excellent *A. aubrietoides*. *Viola gracilis* is also bearing some of its inimitable flowers, and close by is a newcomer, the deliciously fragrant, clear blue *St. Helena Violet*, a charming little thing, none the less fascinating, perhaps, because no one seems to know its history.

Lithospermum rosmarinifolium, which has been flowering since Christmas, still bears a few blooms, despite many weeks of frost, sleet, rain, snow and frost again in most trying alternation. A word of encouragement must also be offered on behalf of the ever-trustworthy *Pulmonarias*. These are not flowers one can ever love, but the plain-leaved *P. azurea* is a really pleasing blue in some lights, and *P. angustifolia* a good woodland plant. These and others of their tribe—the large and rosy *Mrs. Moon*, to mention one more—are seldom cast down by the most inclement weather, and for that we are thankful.

How different is the fate of the luckless *Anemone Pulsatilla*. For at least a month its flowers have lain huddled and half-awake in woolly wrappings which ought to gleam like iridescent silk, but which, instead, have borne a nearer resemblance to the tatters of a superannuated mop. It is not often in our climate that the Pasque Flower appears otherwise than as a silent protest to an ill world—and bell glasses we abhor.

Anemone blanda, gentle as it is patient and beautiful, has spread its blue rays to the rare sunshine and the hardly less lovely *A. appennina* has also marked such grateful interludes. *A. nemorosa Robinsoniana*, larger and exceedingly lovely in the softest of blue lavender, comes a little later, to be in time, it would seem, to "knock out" its rival sisters of the *nemorosa* family. This, however it will never quite succeed in doing, for surpassingly beautiful as the colour of *A. n. Robinsoniana* undoubtedly is, our Wood Anemones in all their divers forms are beyond comparison. So also is the chaste little *A. trifolia*, which I first saw carpeting the ground beneath some Douglas Firs in Mr. E. C. Buxton's garden. This is always a certain early bloomer here, the first of the ivory-white flowers appearing towards the end of March. A rapid spreader, *A. trifolia* is most suitable for growing about the margins of shrub-beries or in the woodland. Any soil seems to suit it, and with us it proves a first-rate shade plant, growing under dwarf *Rhododendrons* and other evergreens.

The *Drabas* are not an exciting race, in so far as our acquaintance of them goes. Albeit, to some of them is due their need of praise for the plucky way in which they will come into bloom despite the most adverse conditions. The most faithful

in flowering, as well as the most enduring, are the familiar *D. aizoides*, *brunia-folia*, *Aizoon*, all yellow, and the white *Sundermanni*. Cheerful wee flowers are these to look right into when there is hardly another thing in bloom on the rock-garden slope.

Deserving of the warmest tribute for the manner in which they defy the most dismal of springs are

the several kinds of *Orobanchis* most commonly seen in gardens, and which hasten into their first flowers even before they have half accomplished the growth of stem and leaf. A form of *O. varius* with bright pink wings and a creamy-yellow keel is irresistibly charming, and *O. vernus* in somewhat of the same colour, is another of the best. *O. cyaneus*, which

gives us sprays of pure turquoise blue above its half unfolded leaves is also very precious. Few flowers ask for so little as these Vetches and others of their clan, few so content to be left quite alone where they may come up season after season increasing in bulk and loveliness every year.

North Wales.

A. T. JOHNSON.

PLANTS FOR THE MORAINE

Almost all the alpine treasures enumerated below will shortly be in flower. They may then be selected and, as such plants are always supplied in pots, may be procured and introduced straightway.

THE beginner in moraine gardening generally enquires what plants will flourish in the moraine. He asks his local nurseryman, it may be, if a certain species which he fancies will "do" in the moraine. The reply is almost certain to be "yes!" and his little moraine garden becomes choked up with plants which certainly flourish exceedingly, but which would thrive in other positions far easier to construct and to maintain.

With a few exceptions, which merely serve to prove the rule, all rock plants will grow on the moraine, provided that the stone of which it is constructed suits their individual tastes. There is little doubt that most, if not all, herbaceous plants would flourish under similar conditions, but the moraine being, in the average garden, necessarily very limited in extent, should be reserved for such treasures as cannot be satisfactorily accommodated elsewhere.

Here may be planted the choicer *Kabschia Saxifragas*. All the forms of *S. Bursleriana* will, by most alpine lovers, be considered worthy. Others which are unlikely really to succeed elsewhere include *S. - Paulina*, *S. Petraschi*, *S. Boydii*, *S. Boydii alba*, *S. - Faldonside*, *S. Rocheliana* and *S. - Irvigui*. The minute *Saxifraga retusa* should have accommodation here, and if the forms of the larger *S. oppositifolia* do not succeed on the cliff, space must be found for them also. Those who admire the red-flowered *S. Griesbachii* and *S. Stribnyii* must grow them in the moraine, though, even there, they are by no means easy. All the above, if the rock is not limestone, should have old mortar rubble in the compost.

Of *Androsaces*, such comparatively easy plants as *A. sarmentosa*, *A. villosa*, *A. - Chunbyi*, *A. primuloides* and *A. toliosa* will flourish where the air is pure in a foot of moraine compost without the underlying trickle of water. It is useless to attempt the woolly *Androsaces* in contaminated air—at any rate, outdoors. Choicer species such as *A. helvetica*, *A. cylindrica*, *A. Chama-jasme* and *A. sempervivoides* must have the true moraine, though the first two, especially, are more easily grown in the alpine house than on the rockery. *Androsace lactea* likes the moraine as does *Douglasia* (*Androsace*) *Vitaliana*. This last will, in a compost almost all limestone rock, flower and spread freely though it hardly attains the luxuriance which *M. Corrodon* so graphically described at its station on *Mont Ventoux* in Provence. See p. 76.

The moraine is, in our climate, the most suitable place for *Androsace carnea* and its beautiful forms *eximia* and *Laggeri*, but the stone here must not be limestone and the compost, besides, should consist mainly of peat and leaf soil. This peaty section of the moraine will accommodate the yellow alpine Daisy, *Arnica montana*, although this plant has little to recommend it except its alleged difficulty. It might be described as a miniature *Buphtalmum*. Here too is the most likely place for the Pine-barren Beauty, *Pyxidantha barbata*, though the exact requirements of this plant are, in the writer's experience, not exactly understood. Other candidates for the same compost, in as exposed and

hot a situation as possible, are *Silene acaulis*, with its truly sessile variety *excapa* and the nearly related

S. bryoides. So treated, they may be persuaded to bloom with comparative freedom, but it is difficult

THE BEAUTIFUL INDIGENOUS SAXIFRAGA OPPOSITIFOLIA, WHICH USUALLY SUCCEEDS BEST ON THE MORAINE.

AN INVALUABLE MORAINE PLANT, CAMPANULA ALLIONII.

to get the flowers even to approach the colour they display on the Alps. The freedom of flowering of these Cushion Pinks, even on the Alps, varies enormously. It is well worth while to raise a batch from collected seeds and to select and re-select them. Here, too, one may try *Dianthus glacialis*. Frequent top-dressings of fine chippings of peat should be given to this rather difficult species. Other Pinks for the moraine are *D. alpinus*, *D. callizonus* and *D. × calalpinus*, but these have the usual *Dianthus* fondness for the limestone. The brilliant *D. neglectus*, never a long lived plant, will, despite statements often made to the contrary succeed in the moraine and even reproduce itself there from self-sown seeds, but it succeeds as well or better, on the cliff-face in full sun.

That mocker of our hopes, the Alpine King, *Eritrichium nanum*, is said to have been successfully cultivated on the moraine, but it is difficult enough in sphagnum in the alpine house!

Of Gentians, *G. Gentianella* will flourish in the moraine—and many are the amateur gardeners who, having failed satisfactorily to flower it elsewhere, have introduced it—but as, in most gardens, it will grow and flower in the path gravel, one would hardly class it as a moraine plant. The allied forms, *Koebiana* and *Clusii* have no special singularity of appearance or beauty, but, if wanted, the moraine is certainly the best place for them, the former on non-calcareous stone and peat, the latter on limestone or with a plentiful admixture of mortar rubble. *Gentiana angustifolia* is a more noteworthy plant, also suitable for the limestone moraine. *Gentiana verna* is emphatically a moraine plant and personal experience suggests that it flowers more freely on chalk than elsewhere. The same treat-

ment is the best that can be recommended for *G. bavarica*, but it is not a plant one would recommend to any but the enthusiast, being the only Gentian to grow in England. No other Gentians are suitable for the moraine.

If there is a well watered portion of the moraine in partial shade, the charming *Soldanellas* should grow there. All three species—*alpina*, *pusilla* and *minima*—are worthy of culture.

Three tiny *Campanulas* are worthy of (and suited for) the moraine. There are *Allionii*, *Raineri* and *Zoysii*. The first named dislikes lime, but the two latter are plants of the limestone. The chief enemies of these minute treasures are slugs. If these can be kept at bay, their culture is in no way difficult.

A "miffy" treasure which needs constant top-dressing is *Draba (Petrocallis) pyrenaica*. Though said to come from the limestone it does not, in the garden, show any pronounced partiality in this respect. Similar treatment appears to suit the far easier and very beautiful *Potentilla nitida* and its rarer white form and the Mountain Buttercups *Ranunculus glacialis* and *R. gramineus*.

The alpinist will have noticed that many of the plants mentioned are not, in nature, moraine species. The fact is that the artificial moraine is a very convenient method of approximating in our English gardens to the conditions as to soil content and moisture which prevail at high altitudes. Whether a plant will succeed in cultivation and if so, under what conditions it will succeed can only be determined by experiment. Preconceived notions suggested by the conditions under which it grows wild often prove illusory.

(Fig. 2). These sawfly larvæ can easily be distinguished from the caterpillars of a moth by the number of legs. There are fourteen claspers and six true legs, making twenty in all; the larvæ of moths never have more than sixteen legs, and in the case of "loopers," such as the magpie moth larva, which is also found on Gooseberries, only ten.

There are at least three broods of these insects during the year, and each brood may continue

FIG. 2.—THE LARVÆ AT THEIR FELL WORK.

to emerge over a period of several weeks. Thus larvæ of all ages and even eggs may be found on the same bush, and some of the earliest larvæ may have pupated before the latest eggs from the same generation of sawflies have hatched. This, of course, increases the difficulty of dealing with this pest.

When full grown the larvæ fall to the ground and spin parchment-like cocoons just below the surface of the soil. The colouring of the cocoons is very variable, ranging from dark brown to yellow, but they are covered with small particles of earth, which have to be rubbed off before the real colouring can be seen (Fig. 3).

The first brood of larvæ begin to pupate from the middle to the end of May, and the sawflies from these (the second brood) emerge in early June. The second brood of larvæ are often mature by the middle or end of June, and from these a third brood of sawflies is produced in July. The larvæ from these pupate in August, and usually remain in the pupa state throughout the winter, producing the first brood of sawflies the following April; but in exceptional circumstances a fourth brood may be produced in late summer. Under favourable conditions the larvæ

FIG. 3.—COCOONS OF THE GOOSEBERRY SAWFLY. (NATURAL SIZE.)
With and without adhering earth.

THE GOOSEBERRY SAWFLY

During the war the majority of gardens were much neglected. Many injurious insects are thus more prevalent than usual, and among them the Gooseberry Sawfly, which annually does immense damage.

THE attacks of this insect and the damage it is capable of doing are well known all over the country. The Gooseberry is its principal food plant, though Currants are also sometimes attacked, particularly the red varieties. The larvæ are familiar enough to gardeners, but the sawfly itself

is by no means so well known. The female is about a quarter of an inch long and five-eighths of an inch across the expanded wings; the head and front part of the thorax are black, and the abdomen and hind part of the thorax orange yellow. The male is usually much smaller than the female, and not nearly so common. (See Fig. 1.)

The first brood of sawflies appears towards the end of April and during May. The females then lay their eggs on the undersides of the Gooseberry leaves, placing them in rows along the main ribs. As many as fifty have been found on one leaf.

These eggs hatch in about a week, and the newly hatched larvæ feed on the lower epidermis of the leaf and so escape observation at first. In two or three days, however, they eat small holes right through, but still remain on the lower surface of the leaf, each larva holding on to the edge of a hole. They feed rapidly and soon nothing but the main ribs of the leaf are left. The larvæ feed together in companies when young, but disperse more and more as they get older. The presence of a colony soon becomes noticeable by the shoots being completely stripped of their leaves.

When young the colouring is pale green, with the head and tail ends of the body yellow. They soon become spotted all over with black and have a black head; the green colouring becomes much paler, and in many cases is only a greenish white, the green being largely due to the contents of the body. After the final moult they again assume a green and yellow colouring and lose their spots

FIG. 1.—THE ADULT INSECT (× 2).
Male above, female below.

develop rapidly, while cold and wet weather retard their growth, and so may reduce the number of broods in a season. The attack of this pest is very persistent if allowed to remain unchecked.

The larvæ pupate in the soil directly under the bushes, and the sawflies emerge and usually lay their eggs on the leaves of the nearest bushes without flying any distance. Eggs are frequently produced parthenogenically, the male being comparatively rare.

Once this insect becomes established in a garden it will remain there, often only in one part of the garden, and if the larvæ are not destroyed they will recur year after year in ever-increasing numbers unless checked by an unfavourable season.

Spraying with lead arsenate in May is the first measure to take against this pest. At this stage the young larvæ will be feeding on the underside of the leaves, and it is therefore important to see that these are well reached by the spray. Arsenate is unsafe to use after the fruit is well formed,

however, and therefore hellebore powder must be used later. This may be mixed with flour and dusted on the leaves when damp, or the mixture may be added to water and applied as a spray, which is probably the better method. Hellebore is safe to use even when the fruit is fairly large, as it loses its poisonous nature in a few days, whereas lead arsenate should not be used within six weeks of picking the fruit. When the fruit is nearly ready for picking even spraying with hellebore is inadvisable, and it is possible to kill the larvæ when young with weak paraffin emulsion if thoroughly applied several times.

Where only a few bushes have been attacked it is a good plan to remove the soil underneath them to a depth of 3ins. or 4ins. during the winter and replace with fresh. The soil removed should then be burnt to destroy the pupæ it contains. If inconvenient to burn it, it should be deeply buried to prevent the emergence of the flies.

RAY PALMER, F.E.S.

THE RETENTION OF MOISTURE IN LIGHT SOILS

The long spells of dry weather in the summer of 1921 gave a good opportunity for observing the effect of different methods of culture in checking the drying out of the soil. Because such summers are the exception in the British Isles, it does not follow that it is unnecessary to prepare for their possible recurrence; the good gardener must arm himself beforehand against all possible extremes.

THE light soils in the south and east of England suffer in most years from minor spells of dry weather, because their general yearly rainfall is low and they are not well retentive of moisture. Before considering our cultural treatment, we must have a clear picture of what is happening in the soil. In autumn and winter the wet sinks in, gradually soaking in turn soil and subsoil, replenishing underground water supplies, till finally the surplus drains off into streams and deep springs; the moisture rarely evaporates from the surface owing to the low temperature and moist atmosphere, and the main current of the water is downwards.

In spring, winds and bright sunshine, in spite of showery intervals, dry the surface; seeds are sown, crops grow and drink thirstily; days grow warmer and longer, and evaporation increases. There comes a time, unless the season is a wet one, when the winter conditions are reversed, more moisture is lost from the soil than the rainfall can restore, and instead of water percolating downwards, it is drawn up from the subsoil to the surface, where it is lost by evaporation. During fine spells, in summer, plants are more and more dependent on subsoil water, which has to rise from lower and lower levels, as it is drawn on and not replenished, so that we notice how our surface soil dries out inch by inch to a greater depth. Hence, during a drought, in late summer and early autumn, the difficulty is not that there is no moisture anywhere, but that it is at such a depth that it rises more slowly than the plants will use it. A storm under these circumstances cannot saturate the soil to any extent, but it reaches the surface roots of plants, checks the loss of moisture, and gives the subsoil water time to reach the surface. A cloudy day alone, and evening syringing, economise the water supply by diminishing the transpiration of the foliage.

The object of our culture must obviously be, in winter to allow full opportunity for rain to penetrate the soil, in spring to get the surface soil sufficiently dry for a good tilth, and in all dry spells to retain an unbroken connexion between

subsoil water and the top spit, and some protection from evaporation at the surface.

The key to the situation is in the capillary (or hair-like) channels which enable the water to rise against the force of gravity in the same way in which moisture is sucked up by a piece of flannel, the lower end of which is dipped in water. Any loosening of the soil breaks up these channels (like dislocating a set of drain pipes, except that the channels go up and down and not horizontally). Digging has, of course, this effect, and in winter the large spaces it leaves between the clods of earth, make it easier for water to sink into the ground, which also holds more water in a loose state (and will as easily let it go again), and this is a help to the action of frost in breaking up the soil particles.

By the time winter is over and evaporation begins again from the surface, the ground below is packed, and the capillary channels have reformed. This is the stage when the treatment of heavy and light soils should differ, especially when the latter are in an area of low rainfall. The heavy soil requires thorough spring cultivation to break up clods and render it friable; not so the light soil. If this is worked up a good spit deep in the spring, as the gardener who prides himself on good cultivation will long to do, the March suns and winds rob the loosened soil of more moisture than it can afford to lose, nor is this all the mischief. There is another trouble, unseen and unsuspected. The light soil does not readily pack again like a heavy one, and it will be many months before the lower capillary channels reform, unless unusual wet supervenes. The surface, then, having lost its connection with the subsoil water, depends entirely on the summer rains, which are probably insufficient to keep it moist, and it "dries out" badly. This state of things is betrayed by the sponginess of the soil. Farmers overcome this by heavy rolling and gardeners tread the ground or pass a roller over it. In the garden my experience is that the firming does not affect the lower part of a disturbed 10ins. of 12ins., and a whole summer may pass before it consolidates.

During the season of 1921 I saw an illustration of this statement. A piece of land was trenched in

mid-winter and part was raked hurriedly over in spring and planted with herbaceous plants with no further preparation. (The ground had formerly been a grass field and was the site of a greenhouse, and this was the first time it had been worked up). These plants flourished exceedingly, even the moisture-loving *Lobelia cardinalis*, with very few waterings. A further portion, torked deeply in late spring, was dry and loose all the summer, and French Beans growing there in spite of the administrations of the hose, were barely kept alive.

Our first consideration, then, is to dig *early* in order to let the ground consolidate, and also to get as much moisture absorbed as possible. (The difficulty of ground occupied by winter crops will be dealt with presently.)

Secondly, in preparation of ground for seed-beds or planting, the soil must not be disturbed again to a depth of more than 3ins. or 4ins. (A Planet hoe will work it up to a very suitable depth.) If it can be avoided, no digging should be done in spring or summer. The surface should preferably be moderately moist before preparing for any crop, and on no account should dry top-soil be buried.

Thirdly, in spring a moderately fine, even surface should be aimed at (unlike rough winter cultivation). If lumps are not broken up when forking, they should be crumbled down with a rake before they get thoroughly dry and hard. Where there is a good deal of fine silt, the soil is likely to form a hard crust, and it should not be raked very firmly, nor should all the stones be removed. For seed sowing the largest must come off, but not in preparing for planting, except in very stony ground. Remember how soil is always moist under a stone.

Fourthly, unoccupied ground must be stirred whether it is to be cropped immediately or not. It forms a crust and cracks under the influence of March winds and sun.

Fifthly, plenty of humus must be supplied to light soils. The success in giving a good start to seedlings will depend largely on well decayed and finely divided organic material in the drills, or better still, evenly fixed with the surface soil. The residue from previous manuring is not sufficient of itself in a dry time. The best stuff to apply is dry one or two year old manure, leaf soil (thoroughly decayed) or some of the organic manures advertised as substitutes for farmyard manure. Soot should be stirred in with the organic dressing, and salt also for Beet, Carrots, Onions.

It is always recommended not to apply farmyard manure early to light soils. I do not see how it is to be avoided. The loss of ammonia I consider is compensated for by the property of the humus of holding moisture; strawy manure should be in a half decayed condition. Digging must be done early, and most crops require manure *below* their roots to encourage deep rooting. Potatoes may have manure worked in when preparing the ground in spring, and the ground will have to be worked deeper for them than for other crops. (They are an exception.) The plot for roots should be double dug and have manure well mixed into the second spit; as the rising of sub-soil moisture is checked by a wad of manure that is not mixed with the soil.

SUMMER.—The secret of summer cultivation is, of course, for all soils, the gospel of the hoe, the dry mulch of 3ins. loose fine soil being the best method of retaining moisture. A heavy shower consolidates this, the capillary channels reform and a hot sun may soon suck away and evaporate more moisture than the storm brought down. Light showers, like light waterings, followed by hot sun, do more harm than good, unless the surface is stirred again without delay as soon as it is friable. Every hour, the precious moisture is turning to vapour in contact with the hot dry air. Ground

that has a moist surface in sunshine is losing underground water. The matter, therefore, is urgent, moreover, if left too long unstirred, there is the added evil of caking and cracking, and young seedlings, especially, will be harmed if the surface flakes when hoed, instead of cracking. It is a very bad thing, also, to go to the other extreme, and hoe when the ground is so wet that it cuts in slices; there is no fine mulch, and a hard pan forms under the hoe. On trodden ground, as between rows of Peas, a light pricking over with a fork is better than hoeing.

Opinions are divided as to the use of manure or lawn mowings as mulches. In certain situations they are very valuable on light warm soils, as wherever hoeing cannot be done, and where roots are very near the surface, say for Strawberries, newly planted trees, Raspberries; they are sometimes applied with success, in a fine state, to Carrots. I believe great benefit would result from frequent light sprinklings of lawn mowings along rows of Carrots and Beet while young; such as would hoe in easily when dried. A drawback to the mulch is that in long dry spells, the mulch and the soil beneath it will get quite dry, and a shower of rain which might have benefited the roots of the plants, does not even wet through the mulch. A grass mulch requires adding to during the season, but in moderation. End of April or May is early enough to apply them, and the soil should previously be pricked up, cleaned and exposed to sun and air.

Moisture is saved in an indirect way by evening syringing and overhead sprinklings with a fine rose, and this is often more refreshing to plants than a watering. Insufficient waterings without hoeing, dry out the soil and burn the roots of plants, and it is better to hoe without watering than to water without hoeing. *Seedlings* for a time may need waterings every day, and in hot weather the only way to get over the difficulty of scorching is to shade during the day.

GROUND OCCUPIED BY WINTER CROPS.—Winter crops should be thoroughly gone over in autumn, cleaned and pricked up. As far as possible, the soil should be kept open between these crops to allow plenty of rain water to percolate and there should be no weedy ground in vegetable or flower garden, as weeds absorb the wet which ought to sink into the soil. Digging should follow as soon as possible on the finishing of the crop. On no account should the Cabbage tribe be left to flower. Once the flowers open the vegetable is of no further use, and they are great wasters of food and water when in bloom. To help in clearing the ground the latest Celery, Leeks, and heading Broccoli can be lifted and heeled in a shady place, as against the north side of a shed or wall.

Trenches for Peas are best prepared in winter before digging the rest of the plot, on ground previously occupied by Potatoes or roots. Cultivate two or three spits deep, with plenty of farmyard manure mixed into bottom layers, and some basic slag. The sites of the rows should be marked, and the whole of the plot afterwards single dug right through. If the trenches are not prepared till the time of cropping, they must have the lower levels well trodden as work proceeds.

The following table gives suggestions for cropping which avoids any deep cultivation after Christmas, except for Leeks and Potatoes:

<i>Autumn and Winter Crop.</i>	<i>Followed by</i>
Cleared before Xmas	Root crops } Do. } Onions } Double dug.
Late Broccoli	Celery
Celery	Peas—no other prep. but levelling every other row.
Leeks	Potatoes.
Winter Spinach	Seedling Brassicas—surface cultivation, soot and humus stirred in.
Spring Cabbage	June and July Carrots and Beet.
Savoy	Potatoes.

To sum up, the special features of treatment to conserve moisture in light soils are:

- (1) Early digging (before Christmas).
- (2) Shallow cultivation from spring onwards.
- (3) No rough surfaces once winter is over.

- (4) No hard crusts to be left unbroken.
- (5) Finely divided humus near the surface. For Carrots and Beet add soot and salt. For Turnips, bone meal is good at the bottom of the drills.

G. PRICE-DAVIES.

CORRESPONDENCE

WHAT IS A "HARDY" ANNUAL?

SUCCINCTLY a "hardy annual" is a plant of which seeds sown out of doors germinate, the plants blossom, ripen their seeds and die within a period of one year—not infrequently the life cycle is covered by three months. On page 181 "A. A."—one may be forgiven for assuming that the writer belongs to the gentler sex—indicts seed merchants on a baseless charge, since her "complaint" is not a "complaint," but a grumble—a complaint without a cause. The fact that the seedsman has printed on his packets of Clarkia, Godetia or any other "hardy" annual the words "raise in gentle heat" or "sow in a hot-bed in February" places the purchaser under no obligation to do so. The seeds are those of "hardy" annuals which may be sown in the open garden from the end of March onwards to the end of June with excellent prospects of success. If, however, the grower with the essential conveniences cares to

who, similarly to "A. A.," have accepted the "suggestions" as "instructions," and not having the necessary conveniences for indoor sowing have excluded many beautiful plants from their gardens in fear of failure. If it is deemed imperative that cultural directions shall be printed in seed catalogues and on seed packets—which, in view of the admirably lined pages of THE GARDEN and other publications, is widely open to doubt—it should be made quite clear that there are alternative methods of culture, each leading to success, from which growers may make choice according to their individual circumstances and surroundings.—W. H. LODGE.

DOUBLE BEGONIAS.

I SEND you a photograph of my Begonias last season which may interest some of your readers. Being purely an amateur's work and grown in a small space, we were very pleased with the

A CORRESPONDENT'S HOUSE OF DOUBLE BEGONIAS.

sow the seeds under glass much earlier in the season he or she is perfectly at liberty to do so. If the seedsman described a plant as a "hardy" annual and proceeded to say that the "seeds must be raised in gentle heat" or that the "seeds must be sown in a hot-bed in February" "A. A." would have a genuine, as against an imaginary, grievance, for the instructions would directly imply that the plant was a "tender" annual, Celosia pyramidalis and Torenia Fournieri to wit, but I have never known a seed merchant to give such explicit instructions on the seed packet of a "hardy" annual. While supporting the seed merchants against an unjustifiable indictment, one ventures to think that the constant recommendations to sow the seeds of "hardy" annuals under glass are unwise. That superior plants, which will flower earlier in the garden, can be raised from seeds sown in greenhouses and frames is undoubted, but I have known several amateurs

result. We placed the original tubers, early in the year, in shallow boxes containing equal parts of leaf-mould and maiden loam, with a fair proportion of sand. As soon as they commenced to shoot we potted them up, giving them subsequently two further shifts, paying careful attention at each removal to drainage. The final compost comprised good loam and leaf-mould with coarse sand. The plants were kept moist and shaded from the sun, and syringed well over night. The following year we propagated them by cutting the tubers with a sharp knife, dusting well with sulphur and laying cut side down in the shallow boxes. If a tuber is found in spring to be partly rotten, the better part can be saved in the same way. They are Blackmore and Langdon's wonderful strain, a particularly fine one being King Alphonso, but the whole range is wonderful. It is surprising that they are not even more largely grown.—K. DOWLING WALKER.

BORDER CARNATIONS FOR THE BORDER.

MR. A. CECIL BARTLETT'S article on the above subject which appeared recently (page 162) is certainly good in most respects, but I for one fail to agree with him on one important point, because from my experience of the last quarter of a century I consider the application of chemical stimulants at this or any season both unwise and unwanted. If the bed was properly made before planting took place—and there is no better place than that which was properly worked and manured for a previous Potato crop—I consider there is no necessity for stimulants, certainly neither sulphate of ammonia nor superphosphate.

The Border Carnation is not a rank or strong feeder, and such tactics as professional growers of the Perpetual-flowering sorts usually adopt to get their plants to bloom twice in the same year are not only detrimental but unwise when applied to the old Border varieties. As regards the matter of specialists' mixtures, Mr. Bartlett may be right if he is referring to "Perpetuals," but I fancy he would have a hard job to find any Border Carnation specialist offering such mixtures. No such ways, in my opinion, are necessary or advisable, at all events for "Borders" grown in open beds, and I question very much if it be right to adopt such ways for plants grown in pots. The effects of such feeding are soon shown in coarser flowers and "grass," consequently coarse and often diseased stock follow; I refer to fungoid diseases in particular.

There is to-day a strong tendency to believe that all plants grown in garden or field are the better for what is usually called artificial manure. Apart from the present expense of such manures—some of which I call soil wasters—I consider it timely that many of us should think of returning as far as practicable to more natural ways of cultivation; I mean the use of real manure and less "artificial." Some will perhaps say where are we to get the real stuff, I grant it is now more difficult to find, but if gardeners and farmers will adopt ways and means of finding as well as producing it, I fancy there is still a chance of getting a fair if not an ample supply.

My main contention is, put the stuff into the flower-pot or soil before you attempt to take it out, and above all allow Nature to do that. I am a disbeliever in forcing tactics and consider that there are few plants or crops that require extra stimulants during growth if the proper foundation has been laid. I go farther and say that there are many instances where extra feeding (either natural or artificial) is, to plants, practically poison; among such I class the Border Carnation, in fact the Dianthus family generally.

I do not mean to infer that I am against common mild ingredients and fertilisers, such as lime, soot and burnt rubbish (potash salts), which are more or less necessities. Bone meal, too, is a food which I do not call artificial; it is one which may be used with most plants, provided it is applied with discretion.—R. MORLEY, *Woodside Park, N.*

DWARF NASTURTIUMS AS POT PLANTS.

EVER since early in March we have been enjoying the brilliance of Nasturtium cloth of Gold flowering in size 54 pots in a slightly heated plant house. The practice is, I believe, rather unusual, but one worth copying where bright flowers are appreciated during the duller days and at small cost. It came about in this wise. Some seed was sown in an outside narrow border that, owing to the abnormal season, proved too dry to effect germination until quite late in the autumn

Knowing then it was too late for the plants to make sufficient growth to flower before frost would spoil them, the small seedlings were taken up and potted as already mentioned. Of course seed could be sown direct in pots in early autumn, growing the plants on in a cold frame until compelled by the cold weather to take them in a warmer place; but I am not sure if sowing in the open and then potting the seedlings would not make sturdier plants because their removal would check long, tapering roots and tend to produce a more fibrous mass of roots. At any rate I make this suggestion so that anyone disposed to try a few pots of dwarf Nasturtiums for winter flowering may adopt whichever method appeals. Of one thing I am certain, floral gayness in the greenhouse in winter cannot be achieved by a more economical and simpler plant to manage than the Nasturtium here cited, while it also affords a good range of colouring.—C. T. *Amphill.*

[A correspondent at Lingfield sent the Editor for his table a few weeks ago really beautiful sprays of Tropæolum Lobbianum, which proved very lasting. There is no doubt that the so-called Nasturtiums are not grown for indoor decoration to the extent they should be.—ED.]

DAME DAFFODIL.

What! Here again, Dame Daffodil,
Aid in your gown of silken twill.
And stomacher, and gauliered frill?
You take my breath, Dame Daffodil!

And that grand air, Dame Daffodil!
You flick your fan with such a skill,
I tear me you are out to kill
A host of lovers, Daffodil!

To see you dancing, Daffodil,
There, by the stream that turns the mill—
Jig, minuet, gavotte, quadrille—
Is heart's delight, Dame Daffodil!

Who makes the music, Daffodil—
The jet-black bird with the orange bill?
Not his the run, the shake, the trill,
But the Lark's I think, Dame Daffodil!

Who is the Wooer, Daffodil,
Comes hither dancing from the hill?
Hang not your head—I think no ill
Of you and the West Wind, Daffodil!

Come, tell me, tell me, Daffodil,
What says the West Wind, so to thrill
Your pulses, and so full to fill
Your Cup with gladness, Daffodil?

Ah, well, dance on, Dame Daffodil,
You and your West Wind! Dance until
You dance your dance, if dance you will,
Above my head, dear Daffodil!

SOMERS.

ALPINES AND ELEVATION.

I WAS grateful to "Hortulanus" for suggesting that another reason why many alpine plants descend to lower elevations on more southern ranges than they usually do on the high Swiss Alps, is because, as in Britain, "many do not ascend to the top of the mountains, but choose a place lower down where they can get a more continuous supply of moisture and, at the same time, get shelter from the hurricanes of wind which frequently prevail." It happens that to-day, April 17, comes a letter from my friend, George Flenwell, who is now living at Locarno and enjoying the "sub-tropical vegetation" and other amenities of the beautiful Lago Maggiore. He says: "My wife and I were in Italy recently. We went to Varese. Although that district is further south than Locarno, its vegetation was far

more backward and far less 'sub-tropical.' [Of course, the sub-tropical vegetation at Locarno has been introduced.] We came across crowds of Snowflakes growing in the open; whereas in Switzerland I have never seen this hulk except in damp and shady gorges. Also the woods near Varese were wonderfully attractive with masses of Erythronium, scattered among the Hepatica, Primrose, Daphne and Scilla. Very gay indeed upon the peculiarly brick-coloured *débris* of rock. I believe a very interesting subject for our paper would be some official explanation of certain alpine vegetation descending to a lower level on this southern side of the Alps than it does on the northern side. Why should that be? Why should greater heat not drive it higher? For the same reason, I presume, that *Gentiana verna*, in Ireland, is found down by the sea. But what is that reason? Could you at your leisure help me to some reasonable and interesting remarks and information upon that subject?" Had Mr. Flenwell seen the recent notes in THE GARDEN on this subject he would have told me. It is a mere coincidence. He wants the information for the *Journal des Etrangers* of Locarno. It is a remarkable publication of its kind, beautifully illustrated by Mr. Flenwell and with charming photographs; while the Easter number contains a most readable article by our friend, Henry Correvon, "In Lovely Canton Tessin." Any further comments upon this question would be appreciated.—H. STUART THOMPSON, *Bristol.*

NOTABLE NEW DAFFODILS.

THERE were very few outstanding flowers at the Daffodil meeting at Vincent Square on April 11, but of course the weather previous to the Show had been of such a cast-iron nature that good flowers were hardly to be expected. The following are all that I spotted personally, but I will not warrant that no good thing was missed: White Nile (Chapman), a distinct and attractive giant Leedsii, segments pure white, slightly pointed and of fine waxy texture, cup long, rather cylindrical, pale lemon, passing to white. Golden Pedestal (J. L. Richardson, Watford) is a giant Incomparabilis of very perfect shape and uniform bright clear yellow; perhaps the best flower in the hall. Magog (Donard Nursery Company), a very large golden yellow Daffodil of the King Alfred type, but larger; a really fine decorative variety. Silver Chimes, a Tazetta variety of triandrus origin, perianth white, cup pale lemon, many flowers per stem, very sweetly scented; this was exhibited by Mr. J. C. Martin of Truro. Nevis (Chapman), a very beautiful white trumpet, much in the way of White Emperor.—J. DUNCAN PEARSON, *Lowdham, Notts.*

LATE SEED SOWING.

A GREAT many gardeners will be forced this season to sow their seeds late, and some amateurs may be lamenting this, so, for their consolation, I write to give my own experience in this matter. Years ago, when I was an even more foolish amateur than I am still, I used to try to get most of my seeds sown before the end of March with the result that I generally had to sow a great many of them again in April. Now, though this may serve the seedsmen, it does not suit my depleted pocket, and besides, it entails a waste of labour—an ever present consideration in these days of "unemployment" and scarcity of workers! Moreover, time and again I have observed that the later sown seeds, which come up when frosts are past, soon overtake and surpass in vigour earlier sown plants which have received checks that more or less spoiled their appearance and stunted their foliage and growth for the season.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Leeks.—Plants raised under glass in January, having been carefully hardened off, may now be placed in their permanent quarters. Planting may be done on the level or in holes made with a stout dibber, or in trenches prepared as for Celery. In either case the soil should be well enriched and be of a good depth, as Leeks appreciate and repay good treatment. When surface grown, allow about 18 ins. or 20 ins. between the rows so that sufficient soil will be available for pulling up to them to assist blanching.

So now my practice is to trust for early flowers to self-sown ones of the previous summer and make my "regular" sowing somewhat like my father's "regular train" to town when we lived at Surbiton. One morning when I arrived down to breakfast (at which meal I have ever been a certain "donkey-race winner") I found there was some friction about breakfast having been late for several mornings. (Of course, I had not observed nor complained of this for the above mentioned reason). Father said he could not catch his "regular train" if breakfast was late. Said mother, with the air of one seeking information, "I should like to know, Joseph, what time your 'regular' train goes?" Replied father, with that roguish look, which he well knew always disarmed mother's displeasure, "My regular train is the 9.50, but I generally go by the 10.20." My "regular" seed sowing is early in April, but gets finished some time in May.—ANNE AMATEUR.

A CORRECTION.

THERE are two errors in my note on page 168 of THE GARDEN, April 8th. Firstly, an obvious misprint, the name of the island is given as "Chirs" instead of Chios. Lower down "Bonner says" should read "Boissier says." My object in drawing attention to these is to make it clear that the mistakes do not occur in Mr. Elwes' letter, from which I quoted.—W. P. MOORE.

CHEAP TICKETS FOR CHELSEA?

WITH reference to the forthcoming R.H.S. Show at Chelsea, would not it be possible to approach the various railway companies with a view to the issue of special cheap tickets. Even if at the rate of the usual week-end tickets, they would, if available for the three days of the Show, be very welcome. In many gardens wages are at a very low level, but I feel sure many would take advantage of cheaper fares if available. Gardeners, and others interested in horticulture, living outside the Home Counties are the ones chiefly concerned.—(Miss) B. GILBERT.

DAFFODILS IN INFORMAL PLANTING.

I HAVE read with much interest the article on Daffodils in THE GARDEN for April 15. My own experience may be of interest. The field above and the field below this house were yellow with Daffodils every spring in years long gone by. As the population increased they gradually disappeared. The flowers were plucked in bud, and one by one the plants were dug up. As they were no longer of any value to the neighbourhood, I took up most of those which remained and planted them, many years ago, in my garden in a piece of rough grass with an area of about 250 square yards. They have increased year after year and have been a great delight. Last year they flowered very badly, but this year they are marvellous. We can safely estimate that there are at least 25,000 flowers. It is interesting to observe among them a number of self-sown crosses—crosses apparently with Emperor, Golden Spur, the Tenby Daffodil, and one or more of the bicolors. I am half sorry, however, for these crosses, because I do not agree with your correspondent in preferring the beautiful large kinds to our native Daffodil for wild gardening. The fields are very dry. The Tenby Daffodil is not princeps, is it? I thought it was very different.—F. A. STURGE, *Coed Efa, near Wrexham.*

[The Tenby Daffodil is, of course, *Narcissus obvallaris*, not princeps, as inadvertently stated in the article in question.—ED.]

Kohl Rabi.—This turnip-like vegetable may be sown any time after March, but a good time to make a general purpose sowing is about the end of April or early May. From this sowing roots are available for late summer and early autumn usage, and when roots are in late demand two more sowings should be made at intervals of about six weeks. The drills should be 18 ins. apart and when the plants are finally thinned they should be about 6 ins. from each other. To avoid waste, only partial thinning should be done at first, which will allow some of the young roots, really swollen stems, to develop sufficiently to use as the final thinning takes place.

Seed Sowing.—Late Brassicas not yet sown or not in sufficient quantities, should receive attention now. It is always advisable to have an abundance of such plants to choose from. Such a sowing now would include Sprouting Broccoli, Savoys, a selection of Kales and Portugal Cabbage. To those who have not previously tried the Russian Kale, it is well worth such a trial, for the young sprouts which spring up in abundance in the centre of each plant after its heart-like middle has been cut are quite as delicious as some of the Kales.

The Flower Garden.

Herbaceous Borders.—A beneficial operation, where time can be found for it, is the thinning of weakly superfluous growths, thus allowing of a better development of the remaining stems. This practice is obviously hardly necessary with newly planted or freshly divided clumps, but applies more particularly where no such work has been carried out for some years. Particularly ought this overcrowding of growths to be mitigated in such plants as Phloxes, Perennial Asters, Chinese Paeonies and Heleniums.

Dahlia.—The stools of these plants still in resting quarters may be planted now, for by the time such growth is in evidence danger from damage by frosts should be past. Where the stock has been increased by division, cuttings or seed, such should be nicely hardened off previous to planting out.

The Tree Pæony is the first of this family to open its flowers and sometimes in early May, when the buds are unfolding, a sharp frost on one or two nights may considerably mar if not entirely spoil the beauty of the blooms. Where sufficient shelter is not provided by the surroundings a few tall stakes should be arranged for to carry a piece of canvas and thus avert or at any rate greatly reduce the danger. The large gorgeous blooms of this plant are well worth trying to save.

Polyanthus require a long period to develop into strong flowering plants, so where an increase of stock is contemplated seed may be sown now. Sow in boxes of light sandy soil and place in a cold frame or sow directly into a prepared bed in the frame. Shade from sunshine and keep at all times uniformly moist, and when the seedlings are large enough to handle, prick out in good soil on a cool border where they can remain until required for their flowering positions.

The Hardy Fruit Garden.

Disbudding.—This work should be carefully carried out and may be begun as soon as the young shoots are an inch or so in length. With trees which mainly carry their fruit on the young wood of the previous year, such as Peaches and Nectarines, first care should be given to the selection of those shoots which will be retained for this purpose. A well placed basal bud, preferably on the top side, is the main one to select and a couple or so others may be left at intervals, and a leader. Much will depend upon the tree and aim of the cultivator. Strong water shoots should not be encouraged, but where such accompanies a fruit should be pinched at the second leaf, otherwise rubbed off, with the possible exception of one below the chosen growth at the base, which, treated spur fashion, will often yield a good fruit. It cannot however be advised to carry the spur method to much extent on such as

Peaches and Nectarines trained on walls, etc. The Morello Cherry also may be treated in like manner to the above, although it must be admitted in this case that excellent crops may be obtained from a spur trained tree and this method is adopted by some growers.

H. TURNER

(Gardener to the Duke of Northumberland,
Albury Park Gardens, Guildford)

FOR NORTHERN GARDENS.

The Kitchen Garden.

Peas.—To ensure regular supplies of Peas from June until October, sowings should be made every ten days or so. The Giant Marrowfats give the most satisfaction, but care should be taken not to sow too thickly in the rows. On ground which is light or gravelly, shallow trenches should be resorted to, with well rotted dung and plenty of decayed material from the compost heap incorporated at the bottom; this is rich in humus and Peas revel in it. Where the trench system is adopted, surface dressings are more usefully applied during the season.

Planting Onions for Large Bulbs.—Onions raised under glass will now have been duly hardened with a view to transplanting in the open at this time. One of the essential points in growing large bulbs of this highly prized vegetable is to have the ground in the highest possible state of cultivation. Ground that has been double dug and richly manured during the autumn, and which has been subjected to the mellowing influence of the weather, will suit the crop well. Fork lightly over and give a good surface dressing of wood ashes and soot. Mark the ground off in rows 15 ins. apart and allow 6 ins. between the plants in the rows. Retain as much soil as possible on the roots when planting and do not plant too deeply.

Potatoes.—Early varieties which are through the ground should be protected when danger of late frosts is likely. If the haulm is only showing, the soil should be drawn lightly over them. If further advanced, some feathery Spruce branches laid down the rows will afford the necessary shelter. Complete the planting of late varieties at the first opportunity.

French Beans.—Where there is a cold frame to spare, a sowing of this desirable vegetable may now be made and thus relieve congestion in the houses. Sow seed of a free-bearing sort, with a sturdy habit of growth. Sow the seeds in rows 18 ins. apart. The dwarf Butter Bean may also be sown in like manner and will be found an excellent sort both for quality and quantity.

The Hardy Fruit Garden.

Black Currants.—Inspect the bushes to see if "Big Bud" is present. If the disease is at all prevalent in the vicinity it may be noticeable at any time now, hence the need for vigilance. When this disease is detected, cut off the infected parts and burn them. By doing this the plantation, if not exactly cleared of the disease, may be kept free for a considerable period.

Fruit Under Glass.

Early Vines in Pots.—Where the fruit is swelling the vines should be regularly supplied with stimulants, so that no check may take place. If the pots allow for such, give a good mulching of cow manure, as this encourages additional roots and has a beneficial influence on the ultimate finish of the bunches.

Maincrop Muscats.—The night temperature of the Muscat house should now range from 65° to 70° and during the day from 75° to 80°. Admit air when the latter temperature is reached. Muscats revel in strong heat, especially when approaching the flowering stage. When in flower attend to the fertilising, also keep the atmosphere to the dry side until the fruit is set.

Orchard Houses.—Keep a watchful eye on the trees to see that aphid does not get a hold. Keep the syringe going freely on trees that are set. With additional sun heat added care must be taken when watering to see that none of the trees suffers from dryness at the root. A check just now, when the fruit is newly formed, may prove fatal, so far as this season's results are concerned.

The Flower Garden.

Pentstemons raised from cuttings and having been well hardened off may now safely be transferred to their flowering quarters. To obtain the finest results from these choice plants the ground should be fairly rich and moderately heavy. The

Pentstemon proves an adaptable plant for grouping in the mixed border, the small flowered Newbury Gem being specially suitable for this purpose.

Antirrhinums which have been raised from cuttings should also be planted out now.

Sowing Hardy Annuals.—If it is the intention of the cultivator to sow hardy annuals, no time should be lost in having the beds or borders put in readiness for sowing. When judicious selections are made and the plants wisely grouped, hardy annuals cannot fail to give satisfaction, especially if the soil is to their liking. Light loamy soil suits them best. To sow on cold clayey soil often results in disappointment. This difficulty, however, may be overcome by giving the site a surface dressing of old potting soil. Assisted in this way germination is more regular and slugs are less troublesome.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Leonotis Leonurus (Lion's Tail).—This handsome plant is very useful for autumn flowering in the greenhouse, and should be propagated by means of cuttings at this time, as it roots readily in a close case in a cool greenhouse. The young plants should be potted on as they require it and do well in ordinary potting compost. Good specimens require 8in. pots in which to flower, and should be stood outdoors during the summer months, giving Chrysanthemum treatment. They are subject to attacks of red spider, therefore a free use of the syringe is necessary.

Agapanthus umbellatus is an excellent plant for the cool conservatory or for standing outdoors in tubs for autumn flowering. They have a large and strong root system, so require liberal treatment, as they often fail to flower in a satisfactory manner through lack of frequent division. Now is a good time to divide plants that are overcrowded. Large tubs are best to plant them in as they are very apt to split their pots. There are several varieties of this plant, and in addition to the white variety, there is a large variety, known as maximus, with pale blue flowers. Agapanthus Mooreanus is a beautiful plant, much smaller than A. umbellatus, while A. Mooreanus var. minor is excellent for the conservatory stage if grown in small pots or pans.

Astilbe simplicifolia is generally regarded as a hardy plant, but its behaviour outdoors is frequently not satisfactory, though it makes a very charming plant for the cool greenhouse. The plants, as they start into growth, may be divided and repotted, 5in. pots being a suitable size. I find they do best if stood in a cold frame with a north exposure, giving them liberal supplies of water at the root when they are well established.

Saxifraga Fortunei is another hardy plant which is excellent for autumn flowering in the cool greenhouse. It succeeds under the same conditions as indicated for the Astilbe. Outdoors it flowers so late that its blooms, unless protected in some way usually get damaged by frost.

Saxifraga sarmentosa, if well grown in 48-sized pots, proves very charming for the cool greenhouse; it is also very useful as a basket plant. The variety tricolor is very beautiful, but requires a warmer house, an intermediate temperature of some 50° to 55° suiting it best in its younger stages.

Nertera depressa, the so-called Fruiting Duckweed, when covered with its coral-red fruit, is very beautiful in small pots or pans, and as it is nearly hardy it only requires the shelter of a cold frame.

Pilea muscosa (the Artillery Plant) is very useful for edging groups in the greenhouse. If four shoots some 4ins. in length are dibbled into 4in. pots useful plants are soon obtained, as they root readily in a warm house, it not being necessary to put them in a propagating case.

Propagating Hard-wooded Plants.—Now is a good time to insert cuttings of such plants as Heaths. The soil should consist of fine peat and sand, which should be rammed very firm. The pots or pans should be dry and clean, and have ample drainage, i.e., half filled with drainage material. Erica cuttings should be made from small twiggy shoots about 1in. in length; young growth firm enough to prevent damping off is best, and great care must be exercised in trimming off the leaves. The gardener with some experience can pull off the leaves, and this is really better than trimming them with a knife; but Epacris must be trimmed off, taking great care to not tear the bark. The above remarks apply to most of the so-called hard-wooded greenhouse plants; small twiggy growth generally rooting more readily

than large and stouter pieces. When dibbled into the cutting pots the cuttings should be well watered and the can should have a fine rose on it. Allow the pots to drain for a short time before they are covered with the bell glasses. The cuttings are best placed in a case in a cool house and the glasses should be removed and wiped dry every morning. With some practice most of the hard-wooded plants can be successfully propagated in this way. Correa cardinalis and the choicer varieties of Correa speciosa are grafted on stocks of Correa alba. The same stock is also used for the various species of Eriostemons, also for Crowea saligna and C. angustifolia. Some of the choicer Grevilleas that are difficult to root successfully can be grafted on seedling stocks of Grevillea robusta.

J. COUTTS,
Royal Botanic Gardens, Kew.

Holland's Gayest Season.—The well known Dutch bulb house of Anthony C. van der Schoot, Hillegom, Holland, informs us that the best time to see Hyacinths, Tulips, Narcissi, etc., in full flower will be from about April 25 till the first week of May. Boat-trains from London (Liverpool Street Station) for Harwich run every night at 8.30 (except on Sunday), and the steamer arrives at Hook of Holland about six o'clock in the morning. The bulb farms are a fine sight at this season.

A Useful Sprayer.—The Editor has had under trial a spraying syringe especially designed for the amateur with a small garden to whom an expensive instrument is disproportionately costly. This new tool, which is called the "Villa" sprayer, is, despite the low price, thoroughly effective and well made. The nozzle is not detachable, which, of course, necessitates a little extra trouble in case of a stoppage, but with care this should not happen and experiment proved a clearance not to be really difficult. To sum up, this small but strongly made appliance can be thoroughly recommended as exceedingly useful and wonderful value for money.

Edinburgh Botanic Gardens.—In our last issue we referred to the retirement of Sir Isaac Bayley Balfour from the post of Regius Keeper of the Botanic Garden at Edinburgh. We now learn that His Majesty the King has approved the appointment of Mr. William Wright Smith, M.A., F.R.S.E., F.L.S., as Regius Keeper, and also as Regius Professor of Botany and Professor of Botany in the University of Edinburgh. Mr. Smith also becomes King's Botanist in Scotland. Mr. Smith has held many important scientific positions, and he joined the staff of the Royal Botanic Gardens, Edinburgh, as deputy to Sir Isaac some years ago. Mr. Smith will be heartily congratulated on his appointment. In his capable hands the good work done by Sir Isaac should be not merely maintained, but amplified.

Messrs. Alex. Dickson and Sons' Dilemma.—The entire seed business in Southern Ireland of Messrs. Alex. Dickson and Sons, Limited, has been confiscated by the Boycott Department of the Irish Republican Army. On the afternoon of Tuesday, April 11, armed raiders took possession of the metropolitan establishment of the firm, situated at 61-63, Dawson Street, Dublin, carried away all the books of the Company, and ordered the business to be closed down. Orders in course of execution were not even allowed to be completed, and all the Company's book debts and stock-in-trade are at the disposal of the Republican Army. The business is completely paralysed and in a state of absolute chaos at the moment. Under these trying circumstances Messrs. Dickson ask for the kind indulgence of their customers in England, Scotland and Wales, and request that all communications pertaining to the Dublin house should be directed to the Northern headquarters at Hawmark, Belfast. A claim has been lodged with the authorities for damages, amounting to £50,000.

ANSWERS TO CORRESPONDENTS

QUESTIONS AND ANSWERS.—All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

FLOWER GARDEN.

AMARYLLIS ATTACKED (G. H., Huntingdon).—The red tinge to the leaves of the Amaryllis is in all probability due to the presence of bulb mite on the bulbs. This can probably best be dealt with by immersing the bulbs in water at a temperature of 110° Fahr. (not more nor less) for an hour.

VARIOUS PLANTS FAILING (R. E., Birmingham).—The trouble with all these plants has in all probability the same origin. Something has been wrong with the water supply during some critical part of their growth. It may be that they are over-watered; it may be that they are allowed to become too dry; and it is quite likely the effect is produced by something acting months before the symptoms are seen. None of the plants mentioned by our correspondent must be allowed to become actually dry at any season. It may, of course, be that the roots are unhealthy and cannot do their work.

NATURALISING DAFFODILS ("Leamington").—The sites of bonfires in the woodlands would be excellent for planting groups of Daffodils as these would be fairly clear of gross weeds and the ashes will have greatly improved the soil by reason of the valuable potash that has been formed. Of the trumpet Daffodils that are reasonably cheap we suggest Emperor, Golden Spur and Maximus of the yellow sorts; Mrs. Thompson, William Golding and Madame de Graaf of the white trumpets; Empress, Horsfieldii, Princes and Glory of Noordwijk of the bicolor trumpets.

TREES AND SHRUBS.

PROPAGATING CYDONIA (PYRUS) JAPONICA (D. C.).—It is now too late to insert cuttings with any hope of success. The best time is in the autumn, when shoots may also be layered. The salmon pink varieties flower during March and April according to the season and locality, contemporary with the old scarlet species. These handsome flowering shrubs do not require the protection of a wall and may well be used for forming a garden hedge, a method we have often recommended in our columns.

RHODODENDRON QUESTIONS ("Lemington").—The best treatment of the young Rhododendrons that are too "leggy" would be to replant them rather low. They would then root out from the stems. The best manure to promote luxuriance of foliage would be a mixture of leaf mould and stable manure. This could be used freely as a top-dressing and also mixed with the soil when planting—one third of this would not be too much. Well charred wood, which is practically charcoal, from forest fires could with safety and to advantage be used. Rotten wood, if used at all, should be with caution.

THE GREENHOUSE.

NERTERA DEPRESSA NOT FRUITING (F. W., Chislehurst).—To induce the flowers to set and form fruits the plants should be placed in a cool, airy temperature as soon as the flowers begin to expand. Previously to this they may well be kept in the shady corner of the warm vinery. This little plant objects to bright sunshine at any time.

COLOURED FREESIAS (C. H. R., Stirlingshire).—Seeds of coloured Freesia may be obtained from Messrs. Sutton and Sons, Reading, and it will be found that quite a satisfactory proportion come good. The shades usually range from yellow to bronze, bronzy-pink, deep rose and mauve. These coloured Freesias are as vigorous as the older types and if grown moderately cool are most pleasantly fragrant. Seeds may be sown now. We are glad to learn that such success was obtained through the cultural instructions in our "Gardening of the Week."

CLIVIAS (J. H. H., Jersey).—We quite agree that much more satisfaction is obtained by growing the best available strains of all plants and particularly those which require glasshouse treatment. Really good varieties of Clivia may be obtained from Messrs. Cibrans, Limited, The Nurseries, Altrincham, or Messrs. L. R. Russell, Limited, The Nurseries, Richmond. Clivia Countess Bathurst which received the R.H.S. cultural commendation last year was shown by the Earl of Bathurst from his gardens at Cirencester Park.

MISCELLANEOUS.

GRUBS FOR IDENTIFICATION (E. D., Suffolk).—The grubs sent are those of a species of Bibio, one of the larger two-winged flies known often as St. Mark's flies because they appear about St. Mark's Day. The flies themselves do no damage, but the grubs sometimes attack the roots of plants when their usual food—decaying vegetable matter—is not available. The usual cultivation of the garden—digging, hoeing, etc.—will turn them out for birds to eat.

SOME LESS COMMON SPRING-FLOWERING BULBS

Of spring-flowering bulbous plants suitable for informal planting only the Narcissi are used to an extent at all proportionate to their merits, while even for formal beds and borders many excellent kinds are much neglected.

ONE of the quaintest of native plants is surely the Snake's-head, *Fritillaria Meleagris*, with its curious contorted habit of growth, albeit against the time the flowers open the stems are as straight as the proverbial ramrod. The *Fritillarias* not only belong to the Lily family, they are so close to them botanically that with some species the classification is so difficult that they have at various times been placed in both genera! The mottled brownish purple straight-sided bells of the Snake's-head are probably known to most gardeners, but there are numberless gardens in which they cannot be found, which is a pity. They are of the easiest culture, growing in border or rocky either in full sun—not on a sun-parched bank—or in partial shade, but they are perhaps seen to greatest advantage under light shade of trees or bushes. They reproduce themselves very freely from self-sown seeds. The bulbs as collected vary considerably in flower colour, and quite a colour range has now been selected. Two excellent and substantial-flowered varieties are called *Orion* and *Cassandra*, but ordinary seedlings answer admirably for most purposes. There is an albino form which has been so largely propagated in Holland that it is now as cheap as, if not cheaper than, the typical form. Other interesting *Fritillarias* with claims on garden room are—in addition to the quaint old-fashioned *Crown Imperial*, *F. Imperialis*—the yellow-flowered *aurea*, the purplish *pyrenaica*, the various purple *camschatcensis*, the deep yellow *pu dica*, and the pink-flowered rather tall *macrophylla*, but none can, in the writer's judgment, compare with the common Snake's-head for grace and charm.

Flowering at the same season—late April and early May—the *Dog's Tooth Violets* (*Erythronium*) are

also particularly charming plants which no garden should be without. As native woodland plants they are invaluable for half-shady corners in a wild garden or, in a compost containing a good proportion of leaf-soil, a cool exposure in the rock garden. The American varieties are usually supposed to be more difficult to establish than the European ones, but this has not been the writer's experience. Where large quantities are needed for massing the true old *Dog's Tooth Violet* will probably be employed, since it is plentiful and cheap, but where a modest beginning is to be made some of the finer forms should be purchased. Two indispensable ones are *grandiflorum* *Pink Beauty* and *californicum* *White Beauty*. Both have beautiful foliage, and the flowers on established plants often reach 3½ ins. across on stems 8 ins. to 10 ins. tall. No stove plant produces more truly beautiful blossoms or more elegant foliage than these. Other fine American kinds are *Hendersoni*—inferior, however,

to *Pink Beauty*—*Nuttallianum* with clear yellow flowers, and *Johnsoni*, a beautiful rose species. The common *Erythronium* of Canadian woodland—*E. americanum*—is, not only under cultivation but even in its native habitat, a shy bloomer, so should be eschewed. Once happily established even the named varieties, such as the two "Beauties," reproduce themselves true from self-sown seeds.

Scilla sibirica with its brilliant blue flowers all gardeners will know, but it is not used as freely as it might be either for bedding or naturalising. It flourishes under turf as well as the pasture-loving *Daffodils*. There has long been a pure white form, and there is now a pale one—*pallida*—but many will consider the colour of this a little too enfeebled to be effective. If the common *Bluebell* of our woods—*Scilla nutans*—were an exotic, it would no doubt be bought by the thousand for mass planting, but as most folk like to make a distinction between woodland

and garden planting it is only necessary to remind readers of the beauty of the pure white form and the worthlessness of the dirty lilac one which is misnamed "pink." The *Spanish Squills*, *S. hispanica*, so similar in appearance and yet so different, are more largely grown than our beautiful native, but they are far coarser and less graceful.

Uncommon bulbs do not necessarily belong to a genus ill-represented in gardens. The *May and June flowering Bearded Irises* are at present among the most popular of garden flowers, but some of the smaller but not less beautiful species are still too rare in gardens. Such are the early and delightful *Iris reticulata* in its livery of royal purple and gold, and its still earlier form *Krelagei* which flowers in February, the golden yellow *Danfordiae*, and the pale lilac *persica*. These will succeed

AN UNCOMMON RELATIVE OF THE SNAKE'S-HEAD, *Fritillaria pudica*.

THREE TYPICAL ERYTHRONIUMS.
Left to right *Hendersoni*, *Nuttallianum* and *White Beauty*.

THE CHARMING ANGEL'S TEARS—NARCISSUS TRIANDRUS.

in sharply drained soil even under thin turf, but they probably show to best advantage in the rock garden. Lest the omission be remarked, it will be well to refer to the beautiful *N. unguicularis* (*stylosa*) and its forms, with the nearly related *N. cretensis*. These are, however, fairly widely grown where climate permits; unfortunately, these beautiful plants are by no means over-hardy even in the Midland Counties.

As it is with Irises so is it with Narcissi. There are many gardens with thousands of long-trumpeted Daffodils, with Narcissi—*incomparabilis*, *Barrii*, *Leedsii* and *poeticus*—well represented, in which the beautiful Angel's Tears (*N. triandrus*) cannot be found. It may be urged that it is not the easiest of plants to grow, but this reproach can hardly be levelled at the now fairly numerous triandrus hybrids. Even the typical plant, however, is not difficult planted in a westward sloping, rather peaty, stony bed or moraine. The chief requirements of the beautiful *N. cyclamineus*, and the equally lovely *N. Bulbocodium* and its varieties *citrinus* and *monophyllum*, are shelter from winds, which destroy them, and a situation where their delicate beauty may be appreciated near at hand. Two exquisite Spanish species deserve wider culture, the primrose *Johnstoni* Queen of Spain and the white trumpet *moschatus* of Haworth.

No one would suggest that the Crocus is uncommon in gardens, but it is doubtful if even the ordinary Dutch varieties are generally used most advantageously, for, like the Daffodil, the Crocus is seen at its best when used boldly and in as natural a manner as possible. The Crocus species have, almost without exception, more grace and beauty than the Dutch sorts, but they are comparatively seldom met with, though their culture presents no difficulty. Of spring-flowering species the best are *biflorus* *Weldenii* *albus*, white, with a conspicuous red stigma; *Imperati*, violet; *Sieberi*, soft lavender; *Tom-masmanus*, pale lavender; *susianus*, golden yellow; and *versicolor*, white, feathered purple.

It is doubtful if the Grape Hyacinth, *Muscari botryoides*, can truthfully be called "less common," but it may safely be asserted that it is not, in general, grouped with sufficient boldness to make it really effective. Masses of these flowers in shrubbery openings and such like are extraordinarily effective. The beautiful *Heavenly Blue* is, of course, noteworthy, but its long grassy foliage at flowering-time at once differentiates it from the typical plant.

The Glory of the Snow (*Chionodoxa Lucicæ*) has been much more grown and appreciated of late years, but one seldom sees the equally beautiful pure white form, the deeper bloomed *C. sardensis*, or the solitary but large-flowered *C. gigantea* with its azure saucers uplifted to the sun. All these are excellent for the rock garden where their display in early springtime is especially welcome. They may be interplanted among plants which develop their foliage later in the season—among *Aquilegia alpina*, for instance, or *Aubrietias*.

The Tulip species have many of them a grace of blossom unusual in the florists' kinds. Speaking generally, their principal requirement is thorough ripening of the bulbs in summer, best assured in our climate by giving them a south aspect on a rockery or sloping ground. The best known is probably *T. Kaufmanniana*, with large cone-shaped flowers of ivory and red with a beautiful deep orange centre. The April-flowering *Greigi* bears orange scarlet flowers of huge size. It is noteworthy, too, for its handsomely marbled foliage. *Tulipa saxatilis* bears three or more flowers on a stem. Its starry blossoms are pink with a yellow base, and well display the chocolate-coloured anthers. *T. sylvestris* with yellow flowers is the wild Tulip so useful for the wild garden. Very different from the large-habited *T. Kaufmanniana* and *Greigi* are such species as *ingens*, quite dwarf, but with flowers of a brilliant red colour; the *Lady Tulip*, *Chusiana*, with small flowers, white, flecked and striped with rose and a conspicuous violet basal disc; *linifolia*, scarlet, with an almost black base; and *persica*, which usually carries its flowers in threes, golden yellow within, bronze without. The charming crimson flowered (rose externally) *primulina* is less easy to grow than most, but very charming and distinctly fragrant.

THE EVER-IMPROVING RHODODENDRON

THE popularity of Rhododendrons is greatly on the increase and the many expert workers at present devoting their attentions to the species and hybrids of the genus will eventually, without doubt, practically revolutionise the quality of these wonderful plants for our gardens. Unfortunately the climatic conditions of the great homes of the genus differ very greatly from that of our country and excepting in Cornwall and other favoured places, many of the species and hybrids are too tender for successful outdoor cultivation. On the other hand, if as much attention were paid to these shrubs as is given in many gardens to bedding out plants and such like, the cultivator would be astonished at the results

Heavy mulchings of good leaf mould, or if not available, then 6ins. to a foot deep of freshly fallen hard-wood leaves placed over the roots will conserve moisture and provide food. Also pieces of rotten wood placed on the surface eventually form tit-bits. During the growing period, if a drought is experienced, copious waterings should be given once or twice per week, but these waterings must be thorough. Sprinkling a small quantity of water on the surface merely tends to bring the roots to the surface. Strong gales from any point of the compass must also be guarded against. Rhododendrons dislike wind. The effects of cold icy blasts need not be enlarged upon, while even warmer winds have the great disadvantages of destroying the foliage and drying up the plants. The positions

successfully from the beginning of September till the present time, although in December and January the roots are particularly dormant and these periods might in consequence be omitted if convenient.

Over-flowering should be guarded against by flower-bud removal in February and it seems hardly necessary to say that the withered trusses should be immediately removed when over.

By attention to these details and recognising that Rhododendrons require some culture, although little compared to many other flowers, it will be found surprising how in the Home Counties many of the climatic disadvantages may be overcome successfully.

There is no lack of choice in selecting plants as their name is legion, but the following may be termed quite hardy and would form a good beginning to a more extensive selection: Alice, Ascot Brilliant, Bagshot Ruby, B. de Bruin, Bordartianum, Coombe Royal, Corona, Cynthia, Doctor Stocker, Duchess of Portland, Duchess of York, fastuosum flore pleno, G. A. Sims, George Hardy, Gomer Waterer, Ivoryianum, Jacksonii (pink), J. G. Millais, Lady Eleanor Cathcart, Manglesii, Mrs. George Paul, Mrs. J. G. Millais, Mrs. Lionel de Rothschild and Royal Purple. J. B. S.

THE EXCELLENT AND HARDY RHODODENDRON MANGLESII.

obtained. In too many gardens it is forgotten that almost all Rhododendrons, other than the high alpine moorland species, are found in close proximity to, or even under, large forest trees. In consequence too often Rhododendrons are placed in pits in lawns exposed to full sunlight. Again, very little attention is paid to the facts that a Rhododendron requires food and water, that its roots are minutely fine and hair-like, that they are surface rooting plants and that, in consequence, drought and sun are apt to play havoc if precautions are not taken. In the wild Rhododendron forests nature overcomes these difficulties by providing shady foliage and generations of decaying leaf mould. Endeavour must therefore be made to reproduce these conditions as far as may be possible and this may be done to a large extent by selecting a situation in close proximity to large trees, preferably Oaks, where no morning sun will penetrate and where the sun will not fall for more than two or three hours a day. In this way scorching will be prevented, the plants will be less likely to over-flower, spring frosts will be less felt, and a very different result obtained.

chosen therefore should be shady and sheltered as much as possible.

As regards soil, it must be lime free, but otherwise good light loam is most suitable; peat and sand are very good provided liberal quantities of leaf mould are used. In all cases, however, the drainage must be sharp. Rhododendrons will not stand any stagnation at their roots. Deep trenching is necessary and any unkind thing, such as pan, must be broken up and removed. As a rule better results can be obtained from beds, but if pits are adopted, care must be taken to see that they are of ample size and all tree roots must be removed either from the beds or pits. Rhododendrons transplant easily and well owing to their close root formation, but careful ramming is required in planting, especially in light soils. Particular care should be taken to see that the plants do not grow into one another, for their beauty of form is quickly lost, and owing to the ease of transplanting, there is no excuse for this being allowed to happen. Further, when in flower, fresh colour arrangements should always be considered and noted for carrying out at a later date. Transplanting generally may be done

A GOOD PLANT FOR MASSING

SOME time ago a writer in THE GARDEN drew attention to the possibilities of *Salvia virgata nemorosa* as an attractive garden plant, and, finding that Mr. Robinson in his "English Flower Garden" spoke of it as a good plant for massing, I ordered one dozen from Messrs. Barr and Sons. This plant proved so striking that I ordered a further dozen and also divided up the first lot of plants so that now, in the third year, we have 50yds. or so of it in the garden. Robinson speaks of it as "low-growing," but in my experience it averages from 2ft to 2½ft. in height.

That it is a drought-resister is evident from the way that it flourished here last summer. We had rain during the latter part of March and no more, not even a thunder shower until August. Our soil is hot and poor, with gravel below, and apart from a little manure at planting time the plants had no more attention save an occasional good watering. They commence blooming in this part of the country (Cams.) in June and continue until late September. By cutting back the spikes after flowering fresh laterals develop and so prolong the blooming season.

For good effect it must be planted in mass. It is beautiful throughout the whole period of its bloom, but is seen at its best with the glow of the western sun shining through it and lighting up its crimson purple bracts and blue flowers. It is then a truly gorgeous sight.

Another extremely beautiful and easily grown plant is *Nepeta Mussini*, but it must be in mass. I have seen odd plants of it in herbaceous borders and it looks almost insignificant. In this garden it also is a drought resister. The soft mauve flowers and grey foliage are very beautiful. That it is easily grown and inexpensive may be gathered from the fact that starting with six plants six years ago, we have now over 100yds. of it, and we have also given quantities away to our friends. It is undoubtedly a lime lover. It is at its best in May and June and makes a charming edging to beds of Pyrethrums, Lupins, Irises and Lavender. If cut back after its first orgy of blossom it does it all over again about September. E. G.

THE TALLER CAMPANULAS

Few flowers have a more definite place in the border than the Bell-flowers. Those mentioned below are suitable for the middle "reaches."

IN considering the best of the Bell-flowers it is convenient to take separately the tall kinds that are good in flower borders and the shorter growing ones for rock gardening and edgings. Of the taller, the first that comes to mind is the stately *C. macrantha*, a garden form of the native *C. latifolia*, the type has purple flowers, but the white variety is rather the better garden plant. A fine form is known as *C. eriocarpa*. Its height is from 4ft. to 5ft.; the shapely spire of bloom, with its sharply cut and pointed segments, and the regular foliage, make it one of the best plants of early summer. Not only is it first rate in the flower border, but as, in common with the greater number of the family, it has no objection to shade, it is one of the finest plants for such a place as where garden joins woodland, or in shrubbery edges. It will stand for several years, growing stronger year by year. It produces an abundance of seed, sows itself freely and is best grown from seedling plants. Another Campanula of bold growth and with equally large flowers is *C. macrocarpa*, with great bells of a reddish purple colour, also fine both in border and wild.

C. persicifolia has long been a garden favourite, and is one of the best of the June flowers, with its graceful habit and many blooms of white or purple. There are double forms, but it is doubtful whether the doubling, when, as is usually the case, it takes the form of a flattened rosette, is to the advantage of beauty; the best form of duplication is where the bell is neither flattened nor crowded, but has a distinct cup and saucer arrangement. In this, which is known as *coronata*, the flower loses nothing of its grace and distinctly gains in point of interest. It is not as common a plant as one would wish. To keep *C. persicifolia* in good order it is best to divide and replant yearly, as soon as the bloom is over. There is no need to cut the old flower stems; a sharp vertical pull

brings them away, and with them anything that is of no further use to the plant. There will remain several prosperous rooted offsets that should be put out separately and will make good flowering plants for the next year.

A good border plant is *C. lactiflora* syn. *celtidifolia*. A quarter of a century ago it had almost been forgotten, but later years have restored it to favour. It is five or more feet high, with a spreading pyramid of bloom at the top, in colour a washed-out purple inclining to white. Its best use is where a pale, cloudy effect of bloom is wanted as a setting to something of strong colour, such as *Clematis Jackmanni*. There is a pure white variety and another of rather smaller habit in which the flowers are a deeper purple. There can be no doubt about its merit as a garden plant, but it requires very careful and clever staking or to be so placed that it is among other plants that will support it just under the head of bloom, for the whole head is apt to be broken down by weight of rain or of blustering wind. No doubt the increase of size and weight of the flower head in cultivation has put too much strain on the upper part of the

THE TOO SELDOM SEEN CAMPANULA ALLIARIAEFOLIA, ADMIRABLE FOR THE EDGE OF WOODLAND.

INVALUABLE WHERE CLOUDY MASSES OF PALEST MAUVE ARE WANTED, CAMPANULA LACTIFLORA

stem which has not strengthened itself in proportion. The plant lasts for several years; seedlings self-sown often appear, perhaps too far forward in the border. When this happens, the flowering growth can be cut back when fairly forward, an experiment which has proved successful with many other plants and the season of blooming is not retarded.

Another persistent plant among the Bell-flowers is *C. alliariaefolia*, with a central spike about 2ft. high and a quantity of blooming laterals; the numerous white bells have a drooping habit. It is perhaps a better plant for the wood edge than for the border. When established it is no further trouble, for the old plants endure for some years and are sure to self sow with a sufficient though moderate number of successors. *C. pyramidalis*, so grandly grown as a biennial in pots by all good gardeners, is apt to be overlooked as an outdoor plant. Its best place is a joint in a cool wall where it becomes a perennial and will probably seed itself. It is best to sow the seed in a limy compost in a joint low down and await the result.

Canterbury Bells have long been with us as indispensable biennials, and nothing can be finer in the late summer, especially in soils that are rich with either loam or chalk; for though good Bell-flowers may be grown in almost any garden, it is in these rich soils that the whole family chiefly delights. But, remembering that *C. Medium* is a native of rocky places in Southern Europe, it also might well be tried in walls. G. JERVELL.

SPETCHLEY STRAIN OF PRIMROSES

The fine exhibit of this strain at the recent fortnightly meeting of the R.H.S. attracted much attention.

THE popularity of the many exotic Primulas—japonica, pulverulenta, rosea Bulleyana, helodoxa and what not—must not blind us to the possibilities of our own Primrose in the hands of capable hybridists. This was brought home to many who saw the Spetchley strain as shown by Mrs. Berkeley at the Vincent Square Hall on April 25. Mrs. Berkeley had selected and brought up quite a representative regiment of plants all at their most effective stage and displaying perfect domes of colour, as shown in the accompanying illustration from a photograph taken last season at Spetchley. The strain, indeed, possesses in unusual degree the qualities of early blooming and late continuing combined with a floriferousness reaching at certain moments and in certain individuals real excess, the plant forming a congested area whose large and sturdy denizens jostle and squeeze each other in their battle for "a place in the sun."

It is a score of years since Mrs. Berkeley turned her attention to the garden Primrose and Polyanthus. Already Miss Jekyll had done much at Munstead, and nothing can excel her selection of whites and yellows. Mrs. Berkeley, while by no means neglecting those colours, sought to develop in endless variety all the really acceptable and satisfying tones of which the race is capable. Orange and brick red, crimson and maroon, pink and mauve, purple and blue, as selfs and as mixtures, have had her attention, so that all men, be they after a full polychromatic effect or sternly insistent on some special hue, will find what they want and of the best if they saunter in spring amid the borders, reserve beds and woodlands of Spetchley. But selection and hybridisation was not concentrated on colour alone. Very many and quite as important other qualities are needed in a prize race, whether it be of man or beast, bird or bloom. There are substance and form, vigour and deportment to be considered and reached before the result can be declared satisfactory. In no detail has Mrs. Berkeley neglected the eugenics of the Primrose. The plants are massive but not coarse. The flowers are large, yet refined and shapely. The stems are long but stout, carrying aloft and erect their brilliant burden of flowers, some of which very nearly reach a diameter of 3 ins., while 2½ ins. is usual enough.

As a wild flower the Primrose is the nation's pride and joy. In competent hands it can, without loss of delicacy and charm, take on new qualities and an almost boundless colour range in the garden. And how easy to grow, how joyous as a harbinger of spring and yet a companion almost till summer-time! It has such a homely, native look, sympathetic to our inherited instincts and racial qualities. A sturdy, balanced, self-confident yet modest, home-loving yet

SHOWS THE FINE HABIT AND IMMENSE VARIETY OF COLOURING OF THE SPETCHLEY PRIMROSES.

colonising creature, readily adapting itself to new conditions and climes, generously responding to wholesome educative processes that give it fresh development and increased scope. We should all rejoice in the workaday Primrose of copse and hedgerow, but we should also watch and minister to its garden ambitions of rising in life, of fulfilling the higher and more varied floral functions, of occupying the seats of the mighty in the halls of horticulture. It "responds readily to treatment," as a doctor says of a well-constituted patient, and we can all get a lot of fun by starting with seed of a good strain and then using our own knowledge and effort in further selection and propagation. We can each of us do much, although not everyone has the assiduous patience, the deft hand, the tasteful judgment that have

enabled Mrs. Berkeley to make Spetchley the home of the blue-blooded aristocracy of the Primrose empire.

TRADITION

Its Value and its Shortcomings.

WE are all people of tradition, and the gardener particularly so, which is no more than to say that we profit from the experience of those gone before us. This is true wisdom, for, though bought wit may be best, it is expensive, and the process of acquiring it is slow compared to that of getting it ready-made from some one else. Tradition, however, followed blindly and without understanding, leads to Rule of Thumb methods, which never give the best results because they break down before any unusual circumstances. In fact, Rule of Thumb is an imperfect substitute for the instinct of an insect, being not so reliable in the first instance, and not so faithfully followed in the second.

Let us see how far tradition is to be followed, and when it is wise to depart from it. Let us suppose, in the first place, that you inherit a good tradition, one of the best; that, as a gardener, you have worked under one of those wonderful masters of the craft who succeeds, by a combination of reasoning and instinct amounting to genius, in bringing every conceivable type of plant to the utmost pitch of perfection.

Having left this master and being in charge on your own account, it would seem an impertinence on your part to make any alteration in your practice until at least you had acquired the standard and experience of your previous instructor. Even if you read of other methods or see them followed, you naturally say that what was good enough for a gardener with drawers full of medals, is good enough for a beginner like yourself. The fallacy of this argument is that your late chief himself would have to change many details of culture to suit altered conditions of soil or climate, or requirements of a different employer. You have also to remember that a genius often has some eccentric ideas which unaccountably prove worthless in the hands of the ordinary mortal; that, no man being perfect, your tradition may include some cultural errors; that progress makes past discoveries obsolete, and that we may learn useful innovations from the experiment or observation of the present.

It follows that tradition, however good, will hamper us considerably and even lead us astray, unless we understand the principles on which it is based, so that we may modify it to suit altered conditions and be able to recognise in what cases it is open to improvement.

There is another source of tradition besides the individual one, and that is the mass of local tradition. This governs dates of sowing and planting, distances between plants and rows of vegetable crops, treatment of the soil and so on. Its value lies in being the result of generations of experience of the peculiarities of that particular environment and soil. Its disadvantage is that it is inelastic and so tenaciously conservative that it lags far behind new improvements and discoveries. This local tradition requires careful sifting, to cast away the dross and keep only what rests on a solid foundation of fact. Even the past masters of our craft are bound by prejudices and have taken-for-granted maxims or procedure, without having themselves tested their correctness. Much misleading information is handed down from one generation to another and accepted as being "what our fathers have told us." G.P.D.

THE SPRING ROSE SHOW

MANY of those who attended the Spring Rose Show at the London Scottish Drill Hall on April 21 must have gone away feeling how very easy it is to have plenty of beautiful Roses in the springtime, for in the hall there were Roses of all types in great abundance and of high quality. Nor were all these lovely blossoms from the great trade establishments, where they are able to select their show blooms from a fair quantity. It is pleasant and encouraging to be able to record that the very best collections of Roses were grown by amateurs. There was not a deal to choose between the exhibits of the President of the Society, Mr. E. J. Holland, and Mr. G. Hammond, who in Section VI received the first and second prizes in the order named, for both had superb blooms, though the first prize dozen were of the more even quality. Mr. Holland showed such as William Shean, Louise Crette and Mrs. Foley Hobbs, while Mr. Hammond had these sorts and such a good bloom of G. Amédée Hammond as to win the silver medal offered for the best amateur's bloom in the Show. The nurseryman's silver medal bloom was a wonderful *Maréchal Niel* by Mr. A. T. Goodwin. This was by nature of a coincidence, as G. Amédée Hammond might well be termed a pale and rather more pointed *Maréchal Niel*. Mr. Goodwin has long been famed for his *Maréchal Niel* Roses, and on the present occasion he surpassed himself.

Mr. H. L. Wettren was another amateur who showed excellent exhibition Roses. His half-dozen of such sorts as *Mme. Méline Soupert*, *William Shean* and *Mrs. E. Mawley* were splendid.

The best cut blooms in the nurserymen's classes were by Mr. E. J. Hicks, whose twenty-four included handsome flowers of *Mrs. Foley Hobbs*, *Gladys Holland*, *Mrs. E. Hicks* and *George Dickson*.

The baskets of Roses did not make such a great display as on some former occasions, but nothing could be finer than Mr. Hammond's *G. Amédée Hammond* or Mr. Goodwin's *Maréchal Niel*. As a display the group of miscellaneous Roses on a staging was very satisfying and surpassed the pot Roses. The first prize group was by Messrs. B. R. Cant and Sons, who displayed generous quantities of the new *Sovereign*, *Ophelia*, *Phœbe*, *Covent Garden* and the chaste single white *Una*. In Mr. G. Prince's second prize collection there were, in *Mrs. C. Lamplough* and *Muriel Wilson*, two beautiful Roses.

The groups of pot Roses included some good sorts, but that which held the eye most was *Paul's Scarlet Climber*, particularly in one of Mr. Hicks' first prize groups. *Ellen Poulsen* was also very bright both here and in a graceful group of *Polyanthas* by Messrs. *William Cutbush* and *Sons*.

The class for new Roses of the previous year is always interesting. The best at the Drill Hall were *Earl Haig*, *Premier*, *Clory* of *Steinfurth*

and *Crusader*. The last named seems a really good dark, velvety crimson Rose, and was to be seen on several stands.

Decorated dinner tables were a great feature of the Show, and had the judging to be done over again later in the day we suspect that the glorious tables of *Hoosier Beauty* and *Richmond*, which by then had opened, displaying a wealth of colour, would have been prize winners. But the table of *Sunburst*, so tastefully arranged by *Mrs. Oakley Fisher*, fully deserved the first prize it received in the amateurs' class; while *Mrs. A. R. Pide* had a very beautiful table of *Columbia* with sprays of *Asparagus plumosus* and *Japanese Maples* in the open class.

NEW ROSES.

Dorcas.—This free-flowering, graceful *Wichuraiana* seedling had many admirers, but did not find favour with the judges. It did not appear to the best advantage when arranged as cut sprays—the more graceful *Polyanthas* never do—but the pot plant was quite attractive. It is said to be a cross between *Minnehaha* and *Orleans*. It bears large sprays of semi-double flowers of soft pink colour with distinct light centres. Shown by Messrs. *English* and *Son*.

Elsie Beckwith.—A glowing H.T. Rose that might well be described as a vivid, deep rose-pink *Richmond*. In common with that useful variety

ELSIE BECKWITH MIGHT BE CALLED A CARMINE-ROSE RICHMOND.

THE GOLDEN-BUFF PERNETIANA VARIETY SOVEREIGN.

it carries shapely blooms on long clean stems and has good foliage. It is recommended for decorative and cut flower purposes. Certificate of merit to Messrs. G. Beckwith and Son.

Mrs. Hornby Lewis.—The dwarfiest of these new Roses, but of vigorous and spreading habit,

THE MASSIVE AND FRAGRANT BLOSSOM OF MRS. HORNBY LEWIS.

carrying its blooms well, above luxuriant, dark green foliage. The petals seem to be stained with an uncommon chrome yellow colour, while the heart of the blooms has the beautiful shading of the fragrant Souvenir de la Malmaison, and it also has a delicate perfume. Certificate of merit to Mr. Elisha J. Hicks.

Mrs. T. English.—A vigorous, free-growing H.T. Rose of apricot fawn colour delicately shaded with salmon pink. The foliage is good and the variety forces well, but it was scarcely up to medal standard. Shown by Messrs. T. English and Son.

Sovereign.—This free-flowering Pernetiana seems to have more colour when forced than it had last summer. The deep golden colour was very heavily flushed with dull cardinal, particularly on the buds. The blooms are pleasantly fragrant, and the stout foliage is of a lustrous green. Certificate of merit to Messrs. B. R. Cant and Sons.

THE MIDLAND DAFFODIL SHOW

THE Daffodil world expects to see a fine display of the choicest varieties at this great Show at the Botanic Gardens, Birmingham, and now that things are settling down somewhat there was great promise of a splendid display. Unfortunately, owing to the lateness of the season, there were no flowers from the North and only a very few from the Midlands, but what was lacking in quantity was more than made up by quality. At this Show there is generally keen competition in

the classes for new varieties and also for the valuable challenge cups.

The Bourne Memorial Cup Class for twelve varieties raised by the exhibitor, brought four entrants, the first prize being awarded to Dr. N. Y. Lower of Presteign, who put up twelve exquisite varieties of the highest quality, including Mrs. Lower, a most refined white trumpet; Mr. F. Herbert Chapman of Rye being second with a choice collection.

The Cartwright Challenge Cup Class for twelve varieties which need not have been raised by the exhibitor, was won by Mr. F. Herbert Chapman with a splendid selection, closely followed by the Donard Nursery Company of Newcastle, Co. Down.

The Walter Ware Challenge Vase for three varieties hunched for market was won by the Donard Nursery Company with Mr. W. A. Watts of St. Asaph, second.

The beautiful White Daffodil Trophy for six varieties of white trumpets brought seven entries; first prize was won by the Donard Nursery Company; second, Mr. F. Herbert Chapman.

The competitive group of thirty-six varieties was won by J. L. Richardson of Waterford with a charming, well balanced lot.

The classes for single blooms were moderately well filled. The first prize for a single bloom of yellow trumpets was awarded to a most perfect bloom of Cleopatra, exhibited by Captain Hawker. White Knight held its own in the white trumpet class, the first prize blossom being shown by J. L. Richardson; a fine flower of Lady Primrose, shown by Donard Nursery Company, obtained first prize in the bi-color trumpets. Mr. Watt's new variety, Brightling, secured first place in the yellow perianth "Incomps." The finest single bloom Barri, with white perianth, was Mr. Mallender's new variety Jessie, named after his daughter which beat five varieties, such as Firetail. The Donard Nursery Company's Tenedos won the Leedsii (4A) Class, while Ivorine, shown by J. L. Richardson won in Class 4B, Leedsii. The favourite Jouquil Buttercup was first in its class. It was shown by J. L. Richardson, who also won first in the Tazetta hybrids with Glorious. The best poeticus was Captain Hawker's Snow King.

Quite a goodly number of varieties were submitted to the Floral Committee for award and awards of merit were bestowed upon the following:—

Orange Glow.—A handsome Incomparabilis variety of large size, perianth canary yellow, the large open corona bright orange with a pretty crimped margin. Shown by Messrs. R. H. Bath, Limited.

Brightling.—Another very beautiful Incomparabilis of good form,

The perianth segments are pale yellow and the short yellow corona is margined with deep orange. Should ultimately prove a valuable market flower. Shown by the Anglesey Bulb Growers' Association.

Sunrise.—A charming and substantial variety belonging to the Barrii section. The creamy perianth has yellow rays and flakes. The cup is a rich orange. Also from the Anglesey Growers.

Cleopatra.—An excellent self yellow trumpet with broad and overlapping perianth segments, Shown by Captain Hawker, Ivybridge.

Magnolia.—A giant Leedsii with stout blossoms for the section; the perianth segments are creamy white and slightly twisted and the rather more deeply tinted cup is well expanded and has a well frilled edge. Shown by Messrs. George Monro, Limited.

Coronation.—A well finished Poeticus variety with a well rounded flower of medium size. The pure white perianth has smooth well overlapping segments. The bright yellow cup is narrowly margined with crimson scarlet. Shown by Messrs. Barr and Sons.

Glorious.—A white perianth Tazetta hybrid with a deep red solid eye; an acquisition. Shown by Mr. J. L. Richardson, Waterford.

Mrs. Percy Neale.—A particularly fine giant Leedsii. The beautiful white perianth is of show flatness, and the cup pale citron. Wonderfully stout for the section both in flower and stem. Shown by Mr. W. F. M. Copeland.

Everest.—An addition to the white trumpet section. From the Donard Nursery Co.

LIKELY TO PROVE AN EXCELLENT GARDEN VARIETY, NARCISSUS BRIGHTLING.

The Birmingham Botanical Silver Medals were won by Mr. J. L. Richardson and Mr. H. R. Darlington of Potters Bar, and bronze ditto by the Donard Nursery Company and Mr. W. F. M. Copeland.

The honorary exhibits are always good at Birmingham, and this season was no exception. Messrs. Barr and Sons of London and the Donard Nursery Company of Ireland well merited the Society's gold medals which were awarded them. Silver-gilt medals were given to Messrs. R. H.

Bath, Limited, of Wisbech, and the Anglesey Bull Growers Association, as well as silver ones to Messrs. Cartwright and Goodwin, Limited, of Kidderminster, J. L. Richardson of Watertford, and W. F. M. Copeland of Southampton.

The Show was well attended as is evidenced by the takings at the gate, which were more than for several years past. Everyone regretted the absence of the Rev. J. Jacob, who is recuperating after an illness and who is now rapidly recovering.

R. Thomsoni. Lady Aberconway, Sir John Ramsden and Mr. G. W. Loder contributed small collections.

The hardier hybrids, which may be termed everyone's Rhododendrons, were splendidly shown by Messrs. Wallace and Co., in a large group of spring-flowering shrubs. The yellow *R. campylocarpum*, *R. Princess Juliana*, a pale blush pink with pretty crimped edges, and *R. Hugo de Vries*, were very fascinating. The last named has Pink Pearl for one parent, which it greatly "favours." Among other shrubs in the hall, *Coroeca virgata* in flower in Messrs. Piper's collection, and the corner group of Mr. R. C. Notcutt, where he had beautiful double-flowered Cherries and standard Brooms, were charming.

Of the many alpine, the outstanding exhibit was by Viscountess Northcliffe, who filled a long table with good plants in pots and pans. These were such Saxifrages, Sedums, Gentians and Armerias as are suitable for flowering in an unheated greenhouse.

Narcissi of all kinds were freely shown. The greatest collection was by Messrs. Barr and Sons, who won a gold medal. They had such gorgeous bright-cupped sorts as Ruby, King's Pirate and Best Man. The pale apricot shading of the corona in Lavender, a Barrii, fascinated many visitors while the pink trumpeted Mrs. Backhouse naturally drew attention.

That decorative variety Flame occupied a prominent place in a collection by Messrs. R. H. Bath, Limited. Almost next door they placed lovely flowers of orange Sir Watkin and Lady Superior, a Barrii bloom with a fiery orange corona. Messrs. Sutton and Sons showed how very decorative the ordinary sorts can be made when they are massed in fair quantity and arranged with taste. The low bowls of such sorts as Rosalie, Tom Thumb, and St. Vincent were delightful.

The Anglesey Bulb Growers' Association had a nice little decorative exhibit, while Messrs. F. H. Chapman, Limited, and Mr. W. F. M. Copeland showed good seedlings.

Carnations and Roses of merit were to be seen in fair quantity. Mr. E. J. Hicks and Messrs. B. R. Cant and Son, showed similar varieties to those they won prizes with a few days previously, and Messrs. Wm. Cutbush and Son had a charming group of Polyantha Roses. The chief Carnations were by Messrs. Allwood Bros., Mr. C. Engelmann and Messrs. Stuart Low and Co.

The Southern Section of the National Primula and Auricula Society had their usual annual small show and many visitors were interested in the quaintly beautiful show Auriculas and more so in the useful alpine. The chief exhibitors were, Mr. Jas. Douglas and Mr. J. Bennet-Poë, while Mr. Miller showed many single and double-flowered Primroses.

The fine strain of Spetchley Primroses, of which a group was exhibited in a corner of the hall, is the subject of an article on page 211. Especially when viewed from a little distance they made a fine display.

NEW AND RARE PLANTS.

Aubrietia Maurice Prichard.—A moderately attractive variety which bears plenty of unusually large pale mauve flowers. Award of merit to Mr. Maurice Prichard.

Azalea Fraternelle.—This and the three following were shown as Kersbergen Azaleas, but, with one exception, they are just large-flowered, very free Mollis Azaleas, though very showy varieties. The colour of *A. Fraternelle* is pale rose suffused with salmon and there is orange-yellow splashing on the upper petals. Award of merit to Messrs. R. Wallace and Co.

Rhododendrons and Auriculas at the Royal Horticultural Society's Hall

THE advertised feature of the R.H.S. meeting on April 25 was Rhododendrons, and this was presumably in the interests of the select band of growers of relatively tender early-flowering sorts. As a Rhododendron Show it did not come up to expectations, and it was evident that most of the exhibitors

further illustrate what a favoured climate West Cornwall enjoys there was, by the Rhododendrons, a gathering of large fruits of Madras Citron from the open air, in the garden of Mr. Howard Fox, Grove Hill, Falmouth.

Mr. E. G. P. Magor, who has long specialised in Rhododendrons in his beautiful valley at

THE HYBRID ROSE-PINK RHODODENDRON AURORA. (AWARD OF MERIT.)

have much to learn before they can make it the success the great beauty of the flowers deserves. There were many lovely blooms in the hall, but often there was no indication as to their nature or objects. Mr. T. H. Lowinsky, Tittenhurst, Sunninghill, brought a great number of large plants in pots. These were mostly beautiful hybrids of *R. Aucklandii* parentage, but all were unnamed. In an exhibit by Messrs. K. Gill and Son, who every season bring branches of excellent blooms from the Falmouth district, one could admire the trusses of flower with understanding and pleasure, for they were attractively arranged and named. Such varieties as *R. Shilson*, Ernest Gill and Gill's Triumph must have made everyone long to possess them. There were many others, including brilliant arboreum seedlings and a generous mass of *Azalea americana*, which may be grown in very many gardens. Almost as to

Lamellan, St. Tudy, Cornwall, brought the most valuable and interesting Rhododendrons from the hybridists point of view under the appreciation of the special committee which judged the collections. In *R. calophyllum* he had decidedly the most beautiful Rhododendron in the Show. It is a compact truss of erect bell-shaped, crystal white blooms, which have a vivid rosy carmine blotch in the centre. The pink form of the same species was also lovely, while the blood red arboreums were most brilliant. A little collection of the small blue-flowered sorts included the beautiful hybrid *R. prostrigatum*.

From the wonderful garden he is making at Exbury, Hampshire, Mr. Leopold de Rothschild exhibited a small collection, and this included such gorgeous sorts as *R. nepalense*, *R. Iverianum*, *R. R. Horsham* and Queen Wilhelmina, with a most charming rose pink cross from *R. kewense* and

Azalea Frederick Engels.—This was the brightest coloured of the many plants on view and seemed to be a typical, good Azalea Mollis of vivid salmon-rose colour. Award of merit to Messrs Wallace.

Azalea Chicago.—The colour of this large-flowered variety may be described as being a coppery-orange. There are spots of a darker shade on the upper petals. Award of merit to Messrs. Wallace.

Azalea Thomas Moore.—A large salmon-pink variety shaded with orange-fawn. The colouring changes to clear yellow in the centre. Award of merit to Messrs. Wallace.

Narcissus Brightling.—This very beautiful *Incomparabilis* Daffodil repeated the success it achieved at Birmingham. Award of merit to the Anglesey Bulb Growers' Association.

Narcissus Chinita.—A charming Poetaz variety bearing twin flowers. The perianth is pale yellow and the small corona is a deeper yellow, margined with orange-scarlet. Award of merit to Mr. Leopold de Rothschild.

Narcissus Magnolia.—The chief charm of this large trumpet Daffodil is its Magnolia-like whiteness. The form is perhaps hardly first-class, the perianth segments being slightly twisted. The tube is widely expanded. Award of merit to Messrs. George Monro.

Narcissus Orange Glow.—The glorious *Incomparabilis* variety of large size which received an award the previous week at Birmingham again found favour. Award of merit to Messrs. R. H. Bath, Limited.

Narcissus Mountaineer.—A large bright yellow trumpet Daffodil of good form and with plenty of substance. Award of merit to Mr. W. B. Cranfield.

Narcissus Rob Berkeley.—A very shapely large trumpet variety of slightly drooping habit. The long, regular trumpet is pale creamy white and the perianth is a trifle paler, becoming nearly milk white. Award of merit to Mrs. Berkeley of Spetchley.

Narcissus Xenophon.—A large flowered Tazetta variety. The twin flowers are in form much like loosely made *Barrii* blooms. The colour is orange with a deeper shade to the

corona. Award of merit to the Anglesey Bulb Growers' Association.

Primrose Clarkson.—A very uncommon rosy-lake single Primrose, which has an orange eye. National Auricula Society's first class certificate to Mr. G. W. Miller.

Primrose George.—A pretty clear lilac single Primrose which has an orange eye. N.A.S. first class certificate to Mr. G. W. Miller.

Primrose Lingwood Beauty.—A free-flowering rosy-purple variety of good form. N.A.S. first class certificate to Mr. G. W. Miller.

Rhododendron Aurora.—Quite the brightest of all the Rhododendrons in the hall. It has a large truss of widely expanded vivid rose-pink flowers. The green leaves are relatively small, so that a bush in bloom would be a rich mass of flower. Award of merit to Mr. Leopold de Rothschild.

Rhododendron Mrs. T. Weylenberg.—A bright rose-pink shaded hybrid which bears plenty of medium sized trusses of bloom. Shown by Messrs. Wm. Cutbush and Sons.

Rhododendron Souvenir de D. A. Koster.—A brilliant free-flowering hybrid somewhat of Doncaster appearance, but the flowers are of a bright, deep rose-pink colour. Award of merit to Messrs. W. Cutbush and Sons.

Streptocarpus Sutton's Giant Blue.—A gigantic but refined flower, nearly as large as a Gloxinia. The pale blue flowers have a pretty white throat. In spite of the great size of the blooms it is a very free-flowering variety. Award of merit to Messrs. Sutton and Sons.

Angraecum Leonis.—A particularly well grown specimen of this Madagascar Orchid was shown bearing three spikes of white flowers, the flower buds are of a curious green tinge. Award of merit to Sir Herbert Leon.

THE REMARKABLE PINK TRUMPETED DAFFODIL
MRS. R. O. BACKHOUSE.

Catasetum Trulla Dovercourt Variety.—This might almost be termed a Black Orchid, for the stems and flowers are of a deep blackish-maroon colour. When lifted the greenish-yellow lip is seen and relieves the sombreness. Award of merit to Dr. T. Bedford.

Brasso-Laelio-Cattleya Truffantiana Low's variety.—A fine large-flowered hybrid, sepals and petals yellow, tinged bright green; the lip is a vivid carmine-rose. Award of merit to Messrs. Stuart Low and Company.

A USEFUL RHODODENDRON

AMONG the newer Chinese Rhododendrons *R. impeditum* is proving one of the most useful species for the rock and alpine garden. A dwarf evergreen shrub of spreading habit, it produces a profusion of purple flowers about 1 inch across, commencing when the plants are only a few inches high and within two years from the sowing of the seeds. When first introduced by Mr. George Forrest in 1911 this plant was grown for several years as *R. fastigiatum*, and may still retain this name in some gardens. In many respects *R. impeditum* is a better garden plant than the earlier introduced *R. intricatum*, as it not only seems to grow better, but flowers about a month later when there is less liability of damage by late spring frosts. Botanically, among other differences, *R. impeditum* is readily distinguished from *R. intricatum* by the long protruding anthers. Very readily increased by seeds and cuttings, there seems every possibility of this dainty alpine Rhododendron being as readily grown in our gardens as the Heathis and Emz. When increased by cuttings is proposed the plants should be grown under glass, the young growths on these rooting much more readily than shoots taken from plants in the open. The flowers vary from mauve to violet-purple.

A. O.

THE CHASTE TRUSS OF RHODODENDRON CALOPHYTUM.

ARTIFICIAL FERTILISERS

Their Use in Spring and Summer.

THERE are still many gardeners who are almost afraid to use artificial fertilisers, and who, in consequence are finding themselves in difficulties owing to the high cost and genuine scarcity of dung, on account of the rapid supercession of horses by machinery. It is for such gardeners that the present article is written, not for the man who has used artificial fertilisers for the last twenty years, for he, of course, will "know all about it."

From this time forward until about the middle of September artificial fertilisers should be in full use. It is often the early and the late applications that count most. Crops can be rushed through a danger period or pushed on to be ready for a certain date. One cannot do this with liquid animal manure whatever anyone may say to the contrary, and one certainly cannot get the beauty of colour in either flowers or vegetables without "artificial" that one can with them.

Like almost everything else, artificial fertilisers have been classified and, if I may say so, over-classified. Nearly every garden writer has some pet classification of his own. He either classifies them as regards the crops that they benefit most, or as regards their solubility in water, or, again, as to the metals of which they are compounds. The present writer would like to abolish all this over-classification, which makes the subject confusing and so often leads to disaster in the case of the inexperienced. Let them be divided into four great groups and stick to that.

The most important group is that of which the principal ingredient is nitrogen. Nitrogenous artificial fertilisers comprise nitrate of soda, sulphate of ammonia, nitrate of ammonia, nitrate of lime and a few others. All are very soluble in water and remarkably quick in action. They produce leafage and nothing else, therefore they should not be used for flowers or vegetables where undue quantities of foliage are undesirable. If, however, crops are wanted to make leaf growth, they should be given nitrogen in one of the forms named above, using it at a rate not greater than 1oz. to the gallon of water or half an ounce to the square yard.

The second group is that of potash manures. Potassium itself is a metal which few gardeners have seen and none need want to see. Its salts, however, are exceedingly useful; in fact, such crops as Potatoes and, indeed, many roots can hardly be grown to perfection without them. Being a metal, potassium combines readily with acids, and one of its compounds, saltpetre, is often used as a nitrogenous manure. In reality, however, it can be used for supplying both potash and nitrogen to the soil, and it will be noticed that it does not make plants "run to leaf" to the same extent as a purely nitrogenous fertiliser. Phosphate of potash is another of its combined salts, but this will be treated in the next section.

Beyond these there are two salts of potash for our use, namely, sulphate of potash and wood ashes, which contain a percentage of carbonate of potash. I need hardly give particulars of the value or use of wood ashes since even the veriest amateur understands it. Sulphate of potash is a valuable fertiliser for application throughout spring and summer. It may either be used dry at the rate of 1oz. to the square yard or in solution at the rate of 1oz. per gallon of water.

The third group of artificial fertilisers consists of those supplying phosphates to the land. I have already mentioned phosphate of potash in this connexion, but it is not recommendable

for general use owing to the difficulty of storing it. It has a disagreeable habit of deliquescing, and must therefore be kept in a damp-proof tin if it is to be stored at all. About a quarter of a pound of phosphate of potash is ample for a 10-gallon cask of water.

Among other phosphatic fertilisers superphosphate of lime is probably the best known, and an effort should be made to obtain a sample with the highest possible percentage of solubility. There is always a considerable amount of superphosphate which will not dissolve, and it is therefore a good plan to make up a stock solution and allow the sediment to settle. If a pound of superphosphate of lime is dissolved in a tub of water holding about 8 gallons and then one part of this stock solution used with every two parts of water, a liquid fertiliser quite strong enough for ordinary purposes will be the result. It does not pay to give superphosphate too strong on account of its being a very acid manure. While potash fertilisers increase quality, phosphates induce earliness.

The last group consists of general artificial fertilisers. One of these, which deserves carefully experimenting with, is sulphate of iron, as it intensifies the colour of both flowers and foliage. In large doses it is very poisonous, but I have successfully used it up to about half an ounce to the gallon of water. E. T. ELLIS.

OLD CONNA HILL GARDEN

ENGLISH visitors who cross the Irish Channel from Holyhead to Kingstown, now called Duo-loughaire, are familiar with the two Sugar Loaf Mountains behind Bray Head. Old Conna Hill lies on the south-east slope of the County Dublin facing these peaks, and a more beautiful situation for a garden would be hard to find. Climate and soil are alike favourable; it is two miles from the sea, sheltered from cold winds, and has a rich loamy soil. Added to all this, two generations of good plantmen for owners have made this the most desirable of all gardens in County Dublin. The following plants were noted during a visit to Captain Riall on March 5: In the shrubbery *Castanopsis chrysophylla*, a fine tree 25ft. high, the beautiful golden underside of the leaves very attractive as the branches swayed in the wind. *Jasminum primulinum* has grown into a thick bush, covered with bright red buds which open into yellow flowers the size of a shilling, with a frill in the centre which makes the flower look like *Narcissus odorata* fl. pl. This tender shrub grows in the open without protection of any kind. A very brilliant pink *Rhododendron*, a dwarf hybrid, with apparently *R. Nobleanum* blood, in a group of four, makes a gay patch. *Rhododendron argenteum* Falconeri, Keysii, Thomsonii, fine healthy specimens, lead to the garden door, which, when opened, shows an avenue of *Cordylines* in front of Yew hedges, framing a beautiful view of sea, sky, Bray Head, the two Sugar Loaf Peaks and stately Douce Mountain.

Turning one's eyes to the garden there is a big stretch of wall covered with plants of *Mimulus glutinosus*, not yet open. Next to it *Cantua dependens* or *buxifolia* which, although the date be March 5, has put forth two of its brilliant rose and yellow flowers, long tubular in shape, opening into expanded mouths. *Dendromecon rigidum*, also, is in flower. This plant is against a 15ft. stone wall; its beautiful grey foliage stands well above the wall. Captain Riall says there is not a month of the year that it is without some of its lovely shining yellow butter-cup like flowers. *Habrothamnus* or *Cestrum fasciculatum* spreads its branches for yards

on the wall, its hard looking dull green leaves a great contrast to the dark shining foliage and brilliant tan bark of the trunks of two big trees of *Myrtus Luma*, covered with white flower buds now, which later in the year are followed by dark wine-coloured fruits. *Myrtus Ugni* fruits very freely here. It is made into jelly at Old Conna Hill, and very good jelly it is. *Callistemon coccineus*, the Australian bottle-brush, is not an uncommon plant out of doors in Ireland, but it seldom attains to 8ft. in height. I have seen this plant in summer when it is covered with its bright red flowers, which are very like the queer little bottle-brushes used in children's nurseries.

Daphne Dauphina is not often seen, though its relations *Mezereum*, purple and white, are in nearly every garden. Captain Riall's shrub of *D. Dauphina* is a gnarled old warrior, with a twisted stem; it spreads 6ft. wide and is covered with reddish-mauve flowers and dark glossy green leaves. It is endowed with the strong sweet *Daphne* scent, almost as good as *D. indica*. *Daphne Blagayana*, a beautiful dwarf alpine shrub, flourishes. It is a straggling grower, the leaves forming a rosette-like tuft at the tips of the branches encircling thick clusters of fragrant white flowers. It blooms freely and for many weeks. The sole secret of success with this plant is to keep the branches well layered with stones, and to plant it in a fairly shady place. It likes a well drained spot.

Rhododendron futescens is a pale yellow-flowered Chinaman, with the thin twigs, narrow leaves and upright growth so distinct from the bushy habit of the Himalayan hybrid type. *R. moupinense* is another delightful Chinese species. It is very dwarf in habit, its large delicate white flowers stand out in relief from its evergreen leathery oval leaves. In most gardens it is well to give it a little protection at night. The flowers open so early in February they are destroyed by even a slight frost. It gets no covering at Old Conna. In a group of this lovely species grown from seed which came from a Wilson collection, there is one remarkable plant with very deep rose-coloured buds, the open flowers white inside with bright rose-coloured backs to the petals. A few buds were carefully packed and sent to Mr. Williams of Caerbays who stated that he has had several similar seedling forms, some of which were of great beauty, and that some of them came true from seed, which is a point of much interest.

Fabiana imbricata (Peru) lives quite unprotected and is already covered with flower buds. *Diosma ericoides* (Rutaceæ), a native of South Africa, was in full flower in an open border, its tiny white flowers have a sweet perfume. *Acacias* do very well in this favoured climate and soil. Many years ago Captain Riall brought home a small pot plant of *Acacia dealbata* from the South of France. It flourished for years in a garden border until it was so badly smashed by a big wind it had to be cut down to the ground. It was 30ft. high with spreading branches. Every March it was smothered in clouds of feathery yellow flowers and many enthusiastic gardeners were bidden yearly to see this lovely tree. Sprays were cut off with no niggardly hand and guests were given sweet-smelling bunches to carry away. From the stump of this gallant tree a strong shoot sprang up, and now a fine young trunk is developing which is flowering well. *Acacia Riciana* (Tasmania) has very dark foliage. *Acacia armata* (Australia) has thick, hard foliage like a miniature Butcher's Broom. *Braeyglottis repanda* was growing well, away from a wall. This beautiful shrub should be tried in many more gardens, but it needs a wall and winter shelter in any but favoured climates. Its grey leaves, with thick woolly underside and beautiful feathery panicles of cream-coloured flowers hanging like those of *Spiraea discolor*, but more cloudy in

effect, are most delightful, and well repay a little attention during the hard weather. Abutilons, white and mauve, grow freely and have a long lease of life. *Embothrium coccineum*, the well named Flame Tree, does well. I have mentioned

only a few plants seen during a short visit. Old Conna Hill, thirteen miles from the city of Dublin, has many treasures in bulbs, herbaceous plants, shrubs and conifers, all well grown and well cared for.
W. PHYLIS MOORE.

SAXIFRAGES OF THE MARITIME ALPS

IN your issue of January 14 last I gave a little account of the Pyrenean Saxifrages. Now let me try to give here an idea of the beauty of those of the Maritime Alps. This chain of mountains is a wonderful centre for the *Euaizooma* group of Saxifrages. The *Kabschia* group is here represented only by some types common to other mountain chains, and the "Mossy" (*Dactyloides*) section which is so richly represented throughout the whole chain of the Pyrenees has here only a local type, *S. pedemontana*, which is also found elsewhere and particularly in Corsica. The types which belong exclusively to the Maritime Alps are *SS. florulenta*, *cochlearis*, *lingulata* and *lantoscana*, with their respective varieties. *S. florulenta* is the most striking of them, and has been rightly called "the pearl of the Alpes-Maritimes." It is well known to alpinists and botanists, as well as to gardeners. It is a veritable jewel of the high altitudes on granitic rocks at from 6,000ft. to 10,000ft. above sea-level, in an area not extending to many kilometres, from the Val Roya to the Tinée Valley. It appears as a real beauty in the crevices of the high granitic walls, and is not at all easy to find. It is useless to attempt to take it from these narrow clefts. The only means to get it is to search for the tiny young plants growing in the stone banks at the foot of the walls. They cannot long live there—they are destined soon to die, because the plant can grow only between rocks. The seeds falling from the cliffs come up regularly, but the plants die after a few years, so that it is not at all reprehensible

to take them out and to bring them away. We grow them at *Floraire* only in a perpendicular position, even in pots, for then we make holes in the sides wherein to introduce the roots.

As regards aspect, *S. florulenta* is very particular, as the dark green, shining and aromatic leaves are disposed in dense rosettes which sometimes become very old. I brought with me once an old plant found dead on the loose stone heap at the foot of a perpendicular cliff where the avalanches brought it after it had flowered, and we reckoned out that the age of it was more than eighty years. The plant makes only five or six leaves per year, and my rosette, which was 40 centimetres long, had more than 500 of them. The plant is a very slow-growing one, and as it is monocarpous (dying after once flowering), as is also *S. longifolia*, the rosette disappears after having flowered. The flower-spike is pyramidal like that of *S. longifolia*, but the flowers are of a very conspicuous rose-purple. The colour is something like that of *S. lilacina*, perhaps rather nearer to the colour of *Megasea crassifolia*, but not at all the hue of *S. oppositifolia*, which is pure carmine. The first time I found it (August, 1908) I was surprised by the beauty of the pyramidal spike of flowers shining upon the dark granitic rocks of the Valley Boréon. The botanist E. Boissier, who grew it at his marvellous garden of Valleyres, had it once in flower—I believe in 1874. A friend of mine at Davos flowered it also, but we have never succeeded in flowering it here. I know of cases in England where the plant has succeeded and flowered well, but they are rare. It must be noted that it is necessary to put it on a north wall and in granite rather than in limestone. We have it here in a wall facing north, and have hopes of flowering it shortly.

S. lingulata is also an element of the flora of these Alps. It only grows on the highest summits, particularly on the north side of the chain. I found it in special luxuriance at the base of the Col de Tende above Linnone and Pesio, where some spikes were not less than 28ins. long and the leaves reached 5ins. or so. It forms large clumps of elegant silver green rosettes, the leaves being broader towards the tip than at the base. The petals are large and of the finest white and contrast elegantly with the dark red glandular stalk. From the end of May until July they form a feature of the landscape. Would that I had the pen of poor Farrer to describe its splendour! No words can describe it; even the peasants of the country come to pay their tribute of admiration. Its culture is a very easy one. It only wants the cliff and a partially shaded aspect.

S. cochlearis is another very distinct species not found elsewhere than on the barren rocks of the south side of the Maritime Alps. While *S. lingulata* remains on the highest altitudes (from 3,000ft. to 7,000ft.), *S. cochlearis* comes rather

low in the same regions. I found it near the sea above Mentone, and Burnat and Boissier found it in Liguria and on the Genevese Apennines. It forms very dense tufts of short-leaved rosettes, the short leaves being thick and spoon-shaped at their tip, but narrow at the base, very glaucous and silvery powdered, particularly at the margins. The flowers are pure white on deep purple or reddish brown stalks. I once found near to Fontau a very small form resembling *S. valdensis*, the same as I saw in an English nursery offered for the Valdesian species. I described it in the

THE RARE SAXIFRAGA FLORULENTA IN ITS NATIVE CLIFF.

Gardeners' Chronicle (December, 1910) as *S. Probyunii*. *S. cochlearis* grows in every garden on sunny rockeries and even in pots.

S. lantoscana is sometimes considered as a form of *lingulata* or even as an intermediary between it and *cochlearis*. It must, however, be considered a true species. (Burnat, "Flore des Alpes Maritimes," Vol. III, pages 260-263.) As cultivated here with the others its characters and requirements are different. The tufts are the largest of all (sometimes they are 2½ft. in diameter) and the flower-stalks are not coloured at all as are those of both other species. The flowers are not quite white, and are, indeed, of rather a dirty colour. The leaves are intermediate between the other two species, as they have the spoon shape of *cochlearis* and the thin base of *lingulata*. It forms dense caespitose clumps of a darker greyish colour than the two others, and is found in a large area extending from the low Valley Roja to the Alps of the Provence. It goes westwards as far as Sisteron in Provence, and forms very large tufts near Le Moutiers de Ste. Marie and in the famous Gorges du Verdon, where I saw the biggest clumps of it I have ever seen. It is found always on calcareous rocks and in dry situations, whether situated in shade or sun, but it grows better on the north side. Engler takes it to be a variety of *lingulata* ("Saxifragales," page 481). There are many intermediate forms between *lantoscana* and *lingulata*, so it is not easy to delimit either species. I found in the high Gorges du Crans more than five different forms between the two types.
H. CORREVON.

Floraire, Chêne Bourg, Geneva.

WHERE SAXIFRAGA LINGULATA GROWS WILD IN THE GORGES DU CRANS.

CORRESPONDENCE

SUCCESS IN TRANSPLANTING.

IN the discussion *re* transplanting Hollies, etc., it seems to me that the chief factor in successful transplanting is missed. That is, the source from which the plants are obtained. Plants obtained from reliable firms may be planted any time from autumn to spring with every confidence—95 out of every 100 will grow. Those secured from unreliable firms, or plants that have been growing in the same position for years, may be transplanted it is true, but in nine cases out of ten will die whether transplanted in the autumn or spring. Therefore, if one wishes to transplant specimen Hollies, Yews, or any other plant, the specimen should be prepared one year for moving the next, the procedure being as follows: A trench should be cut round the whole plant, severing all roots that come in contact with the operator, and should be of such a size as to form a "ball" that can be handled with the strength available. Fill in the trench with light soil in order to induce new roots to form, thereby consolidating the whole "ball." Prepared thus, the plant could be moved the following season with a certainty of success. I am aware that plants such as indicated can be moved without this preparation, but it requires the services of skilled and very able gardeners, with proper appliances for the job, which same very few gardeners possess. Without proper preparation, such as described, the work should be done in early autumn, the earlier the better (in the case of deciduous trees before the leaves have fallen), even if the trees have to be syringed and watered two or three times a day. Do not forget to cut away all crossed or useless wood, remembering that every branch removed is a factor towards successful transplanting.—S. G. SMALLRIDGE.

A SELECTION OF SHRUBS.

I WAS very interested to read "H. E.'s" letter page 157, asking for information about shrub planting. In my opinion this branch of gardening has been very much neglected, especially in small gardens. A judiciously planted bed or border of shrubs is always attractive, as so many varieties are beautiful in leaf, flower and bare stem. What can be nicer in dull winter days than to see the stems of the scarlet Dogwood or yellow barked Willows, and in late autumn the gorgeously coloured foliage of *Berberis Thunbergi*, *Rhus Cotinus* or *Liquidambar*? By careful selection it is possible to have some shrub or other in flower throughout the greater part of the year, starting off with the *Laurustinus* in depth of winter, followed by the golden *Forsythia suspensa* and the sweetly scented but little-grown *Chimonanthus fragrans*. Many of the *Berberises*, too, are early flowering. A place should be found in every garden for the Moonlight Broom and many of the *Spiræas*, such as *Douglasii* (pink), *arguta* (white), *arifolia* (cream) and *opulifolia lutea*. The last-mentioned variety is worth growing on account of its bright golden foliage, especially if associated with the purple-leaved form of *Berberis vulgaris*. *Perowskia atriplicifolia*, with mauve coloured flowers and silvery foliage, is well worth a place. Late-flowering shrubs include the many varieties of *Hibiscus* (*Althea frutex*), *Desmodium penduliflorum* with its panicles of reddish purple flowers, also the blue-flowered *Caryopteris Mastacanthus*, sometimes referred to as the Blue *Spiræa*. After planting very little requires doing beyond thinning out old and exhausted wood and keeping the shrubs from getting "leggy." May I suggest you invite readers to vote for what they think the best

thirty-six hardy shrubs for small gardens. If it could be arranged it would be very interesting.—H. C. P., *Stansted*.

[We have a feeling that readers with small gardens are, generally speaking, more anxious to learn from those with wide experience the best shrubs for their purpose rather than to voice an opinion of their own as to the best selection, necessarily founded on limited data.—ED.]

A BEAUTIFUL WEEPING TREE.

FEW weeping flowering trees can equal the weeping Cherry, *Prunus pendula* (*Prunus Cerasus pendula rosea* of gardeners), the Rose-bud Cherry of Japan. The soft rose flowers are single and of no great size nor special substance, but they are produced with extraordinary freedom. I have in mind a tree worked on a leg of not more than 5ft., which was at the time of purchase considered

A RARE PRIMULA.

I NOTICE in your issue of April 22 you have an illustration of *Primula Fortunei*. Some considerable time ago you had an illustration of this beautiful *Primula* [April 12, 1913, page 182.—ED.] in which both the coarsely dentate leaves and flowers are shown in more detail. It is stated in the letterpress that this is a Chinese species. So far as I have been able to ascertain the place

SPRINGTIME BEAUTY. PRUNUS PENDULA IN BLOSSOM.

a most disappointing specimen. Yet by careful training and judicious thinning from below it now forms an admirable tree, tall enough to walk under in comfort. The enclosed photograph shows a tree with a good leg trained as a bower—which the one previously referred to is not—at New Place, Lingfield, Surrey. The photograph well illustrates the extreme freedom of flower.—H. H.

A VALUABLE EVERGREEN.

A SMALL plant of that dainty evergreen shrub, *Fonicera nitida*, was received from Wisley about eight years ago, and this is now a dense bush of about 7ft. in height and 10ft. across. Until February of this year I had watched in vain for any signs of flowering. I then found it thickly set with tiny buds, and as I considered it very unlikely the blossoms would open so early in the year and in such bad weather as we have had, I took a few branches and placed them in water in a greenhouse and here they seemed quite at home and some flowers opened; also the branches struck root, the smaller the branch the more quickly it rooted. The few flowers which opened were very disappointing after waiting years for

of origin of this plant is uncertain; no one seems to know where it has come from. The specific name *Fortunei* suggests that it may have been introduced into Europe by Robert Fortune, a native of the county from which I write, who visited China four times between 1843 and 1863, and was afterwards Director of the Botanic Gardens at Chelsea. It undoubtedly has been in cultivation for fifty years at least, and was figured by Moore in the *Floral Magazine* for 1806-07 from a plant flowered in the nursery of Messrs. Y. Henderson and Son. It is stated by Mr. Irving that until a few years ago the only specimens known in cultivation belonged to the late Colonel Beddowes, Putney, who had grown it for many years, but it is not known where he obtained his stock. In 1905 Colonel Beddowes presented a plant to the Royal Gardens, Kew, and from this a stock has been raised by division. It is a very easy plant to flower and keep if protected under glass during the winter months and put in a cool, shady place in summer, but it is rarely seen, probably owing to its being a very shy seeder. It can, however, be readily propagated by division. The flowers, which are of a

ilac colour with a yellow eye, appear early in February. It has been stated that this *Primula* is a hybrid between *P. denticulata* and *P. farinosa*, but I cannot agree with this and believe it to be a true species. I have seen good specimens of it both in the cold house at Kew and in the Royal Botanic Gardens, Edinburgh. Some years ago I had several plants and had no difficulty in flowering them.—JOHN MACWATT, *Moreland, Duns*.

[The late Reginald Farrer in his book "The English Rock Garden" describes *P. Fortunei* as a "Chinese species" which "has often been in cultivation," but it is, of course, possible that despite his wide knowledge of Eastern flora he was misled by the specific name and had no definite facts on which to base its origin.—ED.]

GOOSEBERRY BUSHES AS HEDGES.

IN some parts of the country where I was staying recently I noticed that Gooseberry bushes were used as division hedges. There is no reason why they should not be used for this purpose, and if judiciously pruned they should produce excellent crops as well. This is worth a trial, as hedges are, as a rule, very costly and most unremunerative. The large varieties should be used. Pears and some species of Plum are grown for fences, but other fruits might well be tried. The Loganberries and some of the Brambles would make admirable fences if supported here and there with stout stakes. As to ornamental hedges, I noticed recently a Golden Privet hedge dividing a Rose garden. It looked beautiful in the winter landscape.—WALTER SMYTH, *Holywood, County Down*.

NARCISSUS GLANDORE.

I WONDER if Mr. Jacob or some other Narcissus expert would tell us when and by whom the name of Glandore was given to the *Polyanthus Narcissus*, which is so well depicted on the cover of THE GARDEN (April 15). I believe it is indigenous here, for it was the first *Narcissus* I ever saw and gathered, over fifty years ago, from sparse clumps growing at the edges of pastures. These had only two or three blossoms, but brought into the garden and cared for, the size of plant has increased enormously and the blossoms on one stem are as many as in your illustration. The dark green foliage is also greatly strengthened, and the masses my bulbs have increased to have been a wonderful sight this year. A stone font in our church at Easter arranged with them exactly as they grow was a beautiful picture. My long friendship with this *Narcissus* induces me to ask for the origin of the name Glandore. You may not know that Glandore is a coast village in County Cork.—JANE C. CUMMINS.

NOTES ON TOMATO SEEDLINGS.

I HAD much pleasure in reading the "Treatment of Seedling Tomatoes," April 8 issue of THE GARDEN, by the way in which it emphasises the great importance of little things that are so very often overlooked. It is such little items as were mentioned that make so much difference between a real gardener and a careless, indifferent one. There is, however, another item, to wit, the temperature, which is one of the most important. A great number of Tomato seedlings are lost, I fear, owing to the fact that they are hardly kept warm enough, or by an uneven temperature. I have seen batch after batch of Tomatoes almost blue owing to lack of heat, a check from which it takes them some considerable time to recover. From my own personal experience I find the most suitable temperature for seedling Tomatoes to be 65° Fahr. by night and 68° by day, allowing the thermometer to rise a few degrees by sun-heat. May I add that I prefer 2½ in. pots

in preference to 3 in., as the former are less liable to remain sodden with water after "watering in" than are the latter, a very important point, especially during dull weather such as we usually experience during the early months of the year. Again, since a Tomato plant 1 in. to 5 in. high is plenty large enough to plant out in a border, there is little need for a pot larger than a 2½ in. I may state that I scarcely ever lose more than 1 per cent. of my seedlings after they are potted off from the seed-pan.—A. J. P., *Warley Park*.

[Our correspondent's views are interesting but rather discouraging to many amateurs. A night temperature of 55°, or even in exceptionally cold weather 50°, will grow excellent stocky plants. On the other hand, plants grown "soft" in a temperature of 65 will, of course, suffer severely if suddenly exposed to an appreciably lower temperature.—ED.]

PARTNERS.

To a rock, long beaten by sun and storm

On the wind-swept upland ground,

There clings a beauteous living form

Where a Lichen its home has found.

A wondrous alliance here appears

For, on the barren stone,

Two plants unite and live for years

Where neither could live alone.

In the month of May, when the garden glows

With varied charm and power,

The glorious Rhododendron blows,

Queen among shrubs that flower.

Yet here again two powers must meet

To make her beauty known

For, were no fungus at her feet,

No blooms her head would crown.

The seed of a flower of the Orchid kind

In a tropical forest shed

Is doomed to slumber until it find

The needed hyphal thread.

But when they meet the plant is born

And, when 'tis fully grown,

The highest beauty of floral form

It gains—but not alone.

Tho' orchard blossom be fair to see

Unharm'd by frost or rain

Without the work of the humble bee

The promise of fruit is vain.

For the reddening apple by autumn blest

Is born in the time of spring

From a golden grain which finds its rest

By the aid of an insect's wing.

Of growths upheld by partners twain

A nobler still we see:

Science and Practice both maintain

The horticultural tree.

By worthy Practice well supplied

High will it raise its head

With all its branches spreading wide

On roots by Science fed.

A. E. SIMS.

WHAT OF THE DAVIDIA?

IT is now over twenty years since E. H. Wilson, the well-known botanist and traveller, to whom present day gardeners owe so much, sent to this country seeds of *Davidia involuerata* collected in the uplands of Western China. In his fascinating book, "A Naturalist in Western China," Mr. Wilson describes the *Davidia* as one of the most beautiful flowering trees in the whole of the northern hemisphere. Probably many of your readers have more or less established specimens in their gardens, and it would be interesting to know how this tree had adapted itself to this climate. Has

it justified its introduction from a garden point of view? Or is it still too youthful to show its true characteristics. I believe it first flowered at Kew in 1913.—L. BIGG-WITHER, *Wells*.

[The *Davidia*, according to Bean's "Trees and Shrubs Hardy in the British Isles," was first discovered in 1869 by the Abbé David and introduced to Europe by Père Farges in 1897, though Wilson, it is true, sent home a large parcel of seeds during his tour for Messrs. Veitch (1899-1902). There are various types, and the question appears not to have been definitely cleared up as to whether these should all be considered to belong to one species.—ED.]

SHRUBS FOR CHALK SOIL.

I SEND a further list of shrubs suitable for "H. E.'s" shrub garden, which I omitted in my former one. I give them alphabetically. Those marked with an asterisk (*) require sheltered positions: **Abelia chinensis*, slight shade; **Abutilon megapotamicum*, tender, needs winter protection under a south or west wall; *Arbutus Menziesii*; *A. Andrachne*; *Artemisia Abrotanum* (Southernwood), for dwarf groupings in full sun; *Berberis stenophylla* and its forms, *B. s. corallina*, *B. s. Brilliant* and *B. s. coccinea*; *B. semperflorens*; *B. Wallichiana latifolia* (Knightii). Brooms: *Cytisus Andreanus* (Daisy Hill variety), *Dallimorei*, *Newry Gold* and its variety, *Newry Gold* "late flowering." *Cassinia fulvida* (*Diplopappus*) is most valuable for dwarf groupings; **Carpentaria californica*, in a warm, sheltered position; **Camellias*, in a sheltered place or thin woodland, vars. *C. Sasanqua*, *Azuma-Mishiki*, *Onigoromo Mine-no-yuki* and *Mikumiko*; *Cotoneaster Franchetii* (one of the best) and its varieties, *C. F. fructo-maxima*; *C. horizontalis* and *C. h. fructo-sanguinea*; *C. humifusa* syn. *Dammeri*, *C. buxifolia* and *C. rotundifolia*; but of the *Cotoneasters* *C. Simonsii* is the cheapest and is obtainable in large quantities; *Daphne pontica*, and probably also *D. Blagayana* if its particular cultural requirements are known—it likes best to grow through a little mound of stones, added to each year as the plant increases. It is, indeed, the best of all the *Daphne* tribe. Of **Escallonia*s, I think *Philippiana* (white sweet-scented flowers), *langleyensis* (rosy carmine) and *Donard Seedling* (pink) are, perhaps, the best. *Eucalyptus coccifera* is interesting as being fairly hardy in a sheltered position; *Eugenia Ugni*, with its edible fruits, and a companion plant to it, *Myrtus Jenny Reitenbach*, both fairly hardy in the South of England under a wall; *Euonymus radicans kewensis*, a miniature prostrate variety, and *E. r. variegata* (I think there is a variety known as *E. r. var. pictis aureis*); **Garrya elliptica* should on no account be omitted; *Cytisus praecox* and *C. mompessulanus*; *Hypericum chinense* and *H. hircinum majus*. The *Holly*: *Ilex crenata* is an interesting variety much used in Japan in the way we use *Box* edgings. *Jasminum nudiflorum* should not be forgotten, it will ramble over anything or make isolated spreading bushes if left to grow as it will; **Laurustinus*—there is a purple-leaved variety, somewhat tender, once obtainable from Lissadell; *Lauro-petalum chinense*; *Olearias*, never very beautiful, are nevertheless useful for exposed positions; **Phormium tenax* and *Yuccas* of all varieties make fine groups, especially if planted with *Kniphofias* and *Pampas Grass* and in sheltered places also with *Bamboos*; **Titosporum Tobara* is not always hardy, but it is worth trying in all but very cold localities; **Photinia japonica* (syn. *Eriobotrya japonica*), **Photinia serrulata* (syn. *Crataegus glabra*), Chinese Hawthorn, *Pyracantha Gibbsii* and *P. Lalandi*; *Ribes laurifolius*, almost a white variety of the common flowering Currant; *Rosemary* should on no account be omitted, a good

variety is that known as Miss Jessup; Santolina, a dwarf grey-leaved plant useful for dry banks—the variety major becomes quite a bush and has yellow flowers towards the autumn; *Stranværia undulata* is an interesting low-spreading evergreen shrub which would do well on a chalk soil; there are many Veronicas—perhaps the variety *Traversii* is as good as any, and the winter-flowering form of

parviflora; *Viburnums plicatum*, *macrocephalum*, **Carlesii* and **fragnans*; *Weigela Conquète* and *Bouquet Rose*; *Xanthoerans sorbifolia*. There are several *Ericas* that do not thrive on a limestone soil, but *Erica carnea*, *E. Calluna vulgaris* and its garden forms (the best is *E. v. Alportii*) and possibly *E. codonodes* might be tried.—EDWARD SHOOTSMITH.

liquid manure. Always use tepid water when watering or syringing the plants. The foliage should be syringed twice daily, damping all dry surfaces and pathways freely. Support the fruits before they become too heavy. Square pieces of netting with a length of string at each corner are most suitable for this purpose.

The Flower Garden.

Bedding Plants in frames should receive careful attention at this time. Avoid overcrowding and see that watering is not neglected. Move the hardier plants into the open and thus relieve the frames for others less hardy. Keep covering material at hand in case of late frosts.

Biennials.—To have well established plants of Sweet Williams, Canterbury Bells, *Agrostemmas*, etc., before winter sets in, seed should be sown now. Although these may be sown in the open border, the most economical way is to sow in boxes and germinate in a cool frame, pricking out into nursery lines immediately the seedlings are of a suitable size.

Herbaceous Pæonies are gross feeders, so where they are grouped in the border or occupy beds in the flower garden they should be given a nourishing mulch of well decayed cow manure. This is richer than the ordinary stable manure and suits these plants best.

Ecuremocarpos scaber.—Plants of this delightful old-fashioned perennial climber that have been raised from seed should now be planted out. If associated with Canary Creeper or Clematis it is singularly effective, with its profusion of orange red flowers and finely cut foliage. It is hardy in most districts and is partial to a light soil.

Aquatics.—Now is the time to plant Water Lilies and numerous other water plants. In planting *Nymphæas* shallow baskets should be used. Fill with turfy loam and leaf-mould, and after inserting the plants cover the surface with moss and run several strands of tar-string over the top. This keeps plants and soil in position when the basket is being lowered into the water.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Tomatoes.—Plants for growing outdoors should be potted into 5in. or 6in. pots and kept growing in a light position in a house or pit having a temperature ranging from 50° to 60°. Similar treatment should be afforded plants which will be fruited in cold houses after early vegetables, etc., are cleared, as it is an immense gain to start with vigorous plants. When transferring the plants from their pots to the borders it is essential that the latter are thoroughly firmed, as when Tomatoes follow Peas or Beans in a loose compost the setting of the lower trusses of fruits is often disappointing, and the plants also are inclined to make much leafage. Plants in bearing in the early house should be regularly supplied with stimulants and given top-dressings of old manure and loam where it is possible. Remove regularly all lateral growths, and unless there is any particular reason for not doing so, gather all fruits soon after coloration has set in and remove to a medium warm fruit-room. In this way a perfect finish can be relied upon and the plants' energies kept concentrated upon developing fruits.

Potatoes.—Arrange if possible for some protective material to be at hand as the growths of the early plants show above ground. A little soil pulled up round them with the hand will often save a great many. Some dry straw or bracken affords excellent protection and need be only lightly strewn on.

The Flower Garden.

Asters of the annual class are some of the most useful plants we have. All sections are really very good, but for decorative purposes the *sinensis* and ray-floret types are the best. In addition to any possible early sowing under glass, this annual amply repays another sowing outside during May. Plants raised thus and given good treatment will flower splendidly until unfavourable weather spoils them in the autumn. Another point favourable to a late sowing is that some of the plants are most useful for lifting and potting for a cool greenhouse, a point worthy of consideration in small gardens.

Increasing Perennials.—These plants are unquestionably becoming more popular than ever, and with reduced status and expenditure it is not a difficult matter to see why. Plants requiring much time and labour spent upon them under glass before they become fitted for their outside positions must, as a natural order of management, give place to those less expensive to grow. The first half of May is a good time for many perennials to be increased by seed. In a prepared bed of light soil sow thinly in drills about a foot apart, and when sufficiently advanced prick out in ground where they may remain until required. Choose a showery spell for this latter operation if possible. The following are all readily raised from seed: *Aquilegia*, *Alstroemeria*, *Anemusa*, various *Campanulas*, *Chelone barbata*, *Delphiniums*, *Erigeron*, *Geum*, *Gallardias*, *Helianthus*, *Hollyhocks* and *Lupins*.

The Hardy Fruit Garden.

Strawberries.—Plants that have fruited under glass are useful for making an outdoor bed for another season. When it is decided to make use of them in this way it is essential that the plants be kept clean and regularly watered after the fruits are gathered. It is also helpful and enables the plants more quickly to recuperate after cropping if they are placed in a partly shaded position until the planting can be done. By the aid of a pointed stick a portion of the old balls of soil should be reduced and the roots disentangled before placing them in the ground. Plant freely and water the plants afterwards, repeating the latter operation several times if the weather be dry and place a little mulching material round each plant. The bed of plants fruiting this season should have the hoe occasionally plied between

the rows to check small weeds and to allow sun and air to sweeten the soil. A dusting of old soot and of an approved artificial manure will be repaid later on.

Fruit Under Glass.

Border Watering.—The importance of this operation at all seasons in bearing upon the results obtained from practically all fruits cannot be too seriously realised. With lengthening days and increased sun-heat all plants carrying crops require great care to see that, through root dryness, they are not prevented from bringing their fruits to the highest state of perfection. Where crops of Grapes, Peaches, etc., are produced in pots or tubs for early work it is essential that frequent and copious waterings of diluted manure be given to prevent exhaustion, and a liberal top-dressing and mulch also be added. Healthy plants in well drained borders during the next few months will require a thorough soaking every two or three weeks in addition to plenty of good surface waterings during bright days when there is plenty of air circulating.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Beet.—The principal sowing of this desirable vegetable should now be made. To secure a profitable crop Beet should be grown on a rich heavy soil which has been deeply trenched and subjected to liberal manuring the previous season. Freshly manured land encourages coarse specimens, which are seldom fit for kitchen use. Choose reliable sorts, and in gardens where difficulty is experienced with the long-rooted varieties a sowing of the round type should be tried, Sutton's Globe being particularly favoured and of easy culture. Sow in drills from 15ins. to 18ins. apart, thinning out to 9ins. apart in the row. One ounce of seed should be sufficient to sow a row of about 45ft.

Leeks raised under glass for the purpose of growing in trenches will now be ready for transferring to their quarters in the open. Leeks are gross feeders and enjoy plenty of farmyard manure worked into the bottom of the trench. Should the weather be dry water regularly.

Cabbages.—Plant out successional batches as ready and keep the hoe going among early crops.

Celery Trenches.—Have these prepared at the earliest opportunity, placing a liberal quantity of manure at the bottom of the trench and incorporating it with the soil. Where the natural soil is lumpy or clayey it is of considerable advantage to add a quantity of old potting soil, as this gives the young plants an encouraging start and facilitates the work of planting.

Mushrooms.—Make up a good-sized bed now so that generous supplies may be obtained during the month of June. See that the bed is in proper condition for spawning and do not rely on old spawn. Obtain the best spawn that can be procured.

The Hardy Fruit Garden.

Strawberries.—Before applying a mulch to Strawberry beds run the Dutch hoe between the rows. This aerates the soil and also checks the growth of weeds.

Peaches and Nectarines in bloom should be hand fertilised, as insect life at this season is not much in evidence, especially when frosty nights are experienced. After the fruits are set a soaking at the roots with soft water will be beneficial, as wall trees seldom get their due portion of the rains owing to their sheltered position.

Fruits Under Glass.

Melons.—The fruits on early batches will now be swelling freely, so should be assisted with weak

CONSERVATORY AND GREENHOUSE.

Cestrums are very useful plants for clothing pillars or for training on back walls of conservatories or greenhouses. *Cestrum elegans* and *C. Newellii* are—or used to be—common plants in gardens, but the beautiful yellow-flowered *C. aurantiacum* is perhaps not so generally known. *C. Smithii*, with pale pink flowers, is of a different type, and is better adapted for pot cultivation, as it naturally makes a dwarf bushy plant. The stronger-growing species are really seen at their best when they can be planted out, although they may be very well grown in large pots, especially if they are kept well fed when they have well filled their pots with roots. They are all easily propagated by means of cuttings. Unfortunately, they are very subject to attacks of green fly, but this may be kept in check if the plants are sprayed frequently with some approved insecticide.

Clerodendron fallax.—This plant is generally regarded as a stove plant, and is usually grown for winter flowering. In the neighbourhood of London fogs usually spoil it during the winter months, so the plants should be grown for the conservatory for flowering during August and September. Plants raised from seeds sown earlier in the year should be potted on as they require it. As it is a quick-growing plant there is still time to raise it either from seeds or cuttings, growing it on in a warm house in a temperature of 50° to 60°.

Clerodendron fragrans fl.-pl. with its white double flowers is worth growing for its delightful fragrance. It is easily propagated either by means of ordinary or root cuttings. Its cultivation presents no difficulty, as it is almost hardy in dry borders at the foot of a warm wall.

Clerodendron Thomsonæ, generally regarded as requiring stove treatment, is really quite happy in an ordinary conservatory. Fine specimen plants can be grown in large pots or tubs, giving them intermediate house treatment while making their growth. When well in flower they should be removed to the conservatory, where they will remain in full beauty for a long time.

Clerodendron ugandense has beautiful blue flowers, and is an excellent plant for the cool conservatory or greenhouse. It should be planted out and grown in bush form, or it may be used for clothing a rafter or pillar.

THE SO-CALLED AMERICAN PLANTS

In perhaps two-thirds of the total number of British gardens "American" plants may be cultivated without special difficulty.

PRACTICALLY every garden on suitable soil has its Rhododendrons and Azaleas. It may probably have a portion—oftentimes not an adequate portion, however—devoted to hardy Heaths, but the remaining members of the great family of lime-haters—American plants as they are generally called—are, as a rule, sadly neglected.

Wherever the natural soil is not pronouncedly calcareous, American plants can be persuaded to thrive. Where Rhododendrons are happy practically all the rest will be at home. If Rhododendrons have not been tried a glance at the vegetation of the countryside should give a good idea of the soil preparation which will be necessary. If any of our native Heaths are in possession the soil obviously is suitable already and the presence of the Whortleberry or Bilberry, as it is called in some localities (*Vaccinium Myrtillus*) is an equally favourable sign, though hardly a better one than a growth of Bracken. Wherever Birches and Scots Firs contribute a considerable portion of the charm of the landscape nothing but a certain addition of humus by means of leaf-soil and spent manure will be necessary to achieve success. If fine Elms are a feature of the countryside a supply of lime is indicated and soil analysis may be called for, but it often happens that the lime-bearing strata—perhaps a stiff loam—is at some little depth and will cause no trouble. Probably two-thirds of the gardens of England might be made entirely suitable for American plants without any great trouble or expenditure.

Having mentioned Rhododendrons, and included Azaleas and Heaths, one has in the view of many gardens practically covered the field of American plants, but there are, in fact, numbers of interesting and really beautiful American plants quite outside these genera.

The *Kalmias*, more often seen than some others, are valuable all the year round for their beautiful foliage, and although their flowers are less showy than those of the Rhododendron, they are very handsome and are produced when the "Rhodos" are over. The Mountain Laurel (*Kalmia latifolia*) has leaves very much like those of a Laurel, although there is something in the gloss of leaf which is different to anything seen in the Laurel family. The flower clusters are freely produced and varieties are to be obtained in which the

flower-colour varies from pale blush to clear rose. Of the other species the dwarf-growing *Kalmia angustifolia* is most valuable. Quite unlike the Mountain Laurel in appearance, its deep red blossoms are also produced in clusters. *Kalmia glauca* has rather handsome glaucous foliage, but its flowers in shades of washed-out purple are produced during Rhododendron time. The small-growing *Kalmia hirsuta* is chiefly remarkable in that its rose flowers are solitary.

Many excellent shrubs with bell-shaped, more or less Lily-of-the-Valley-like flowers, are grouped by gardeners under the genus *Andromeda*, though botanists classify most of them as *Cassandra*, *Cassiope*, *Leucothoe*, *Lyonia*, *Oxydendron* or *Zenobia*. Perhaps most valuable of all are those classed as *Pieris*, of which the most commonly

seen is the early-flowering and compact-growing *P. floribunda*, distinguished by its hardihood and beauty of form. Larger of growth and whiter of flower is *P. japonica*, but it needs a more sheltered situation than *P. floribunda*. An improvement on the last named, so far as the flowers go, is the recently introduced *P. taiwanensis*, of which, however, the hardihood has to be proved. Of the stature of a small tree is *Oxydendron arboreum*, a deciduous species with large terminal panicles reminiscent of *Pieris japonica*. *Cassandra calyculata* is an accommodating species which will flourish on dry banks where little else except, perhaps, the Rose of Sharon (*Hippuricocalycium*) would grow. Its greenish-white blossom is pretty enough, but being carried beneath

THE "MOUNTAIN LAUREL," *KALMIA LATIFOLIA*.

ST. DABEOC'S HEATH, *DABOECIA POLIFOLIA*, A LONG-FLOWERING SPECIES.*PIERIS FLORICUNDA*, BEAUTIFUL IN EARLY SPRING.

the arching shoots like the bells of Solomon's Seal (*Polygonatum*) is not conspicuous. There is a form larger alike in growth and flower called major.

Tiniest of all the so-called Andromedas is *Cassiope tetragona*, with the congested rather "Japanesque" habit characteristic of Arctic plants. Despite the characteristic pure white bells it reminds one of some of the tiny shrubby Speedwells, especially of *Veronica loganioides*. A westerly aspect suits it best, as despite its Arctic origin it resents too much frost and thaw.

A noteworthy deciduous shrub is *Leucothoe racemosa*, which attains a height of 4ft. or so and is smothered in July with quantities of fragrant white flowers in spikes. Flowering a little earlier, evergreen and of a looser habit of growth, *L. axillaris* is also quite a desirable species. *Lyonia ferruginea* is a shrub attaining a height of 6ft. or so, but of little interest, save to the collector, and not over hardy in most parts of Britain.

Zenobia speciosa grows to a height of 3ft. or 4ft. It has characteristic, strongly veined evergreen foliage, and the white bells so characteristic of the family. Still left under Andromeda is *A. polifolia*, a native plant with a procumbent habit of growth, narrow, shining leaves and flowers of a closed bell-shape produced practically all summer. Pink-flowered forms are not uncommon. Closely related American forms vary very considerably both in flower and foliage. Such are, for example, *A.A. canadensis*, *angustifolia*, *rosmarinifolia* and *rubra*.

The Pepper Tree (so called), *Clethra alnifolia*, is a very pleasing and fragrant shrub, with a strong *pendant* for moist soil, which flowers in late summer and early autumn. It attains a height of 5ft. or so. This very desirable shrub is deciduous. Somewhat similar in general appearance and also deciduous, are *C.C. acuminata*, *paniculata*, *scabra* and *tomentosa*. The first named is a plant of colder habit of growth. The evergreen *C. arborea*, also summer-flowering, succeeds only near our

seaboards or milder localities inland. Even so, except in specially favoured spots, it needs the shelter of a wall, which is unfortunate, as it is, indeed, a beautiful shrub.

Gaultheria Shallon is really valuable because it succeeds in shade, even woodland shade, as well as in the open. It produces racemes of pink and

white flowers and edible purple berries. *G. procumbens* is a miniature with not very conspicuous white flowers which are followed by red berries that remain on the plant until spring.

The *Menziesias*, properly so-called, are rather dingy shrubs and scarcely merit cultivation, but the St. Dabeoc's Heaths (*Daboecia*), often listed as *Menziesias*, are wonderfully beautiful, especially some of the new cross-bred forms. *Daboecia polifolia* itself varies from ruddy purple to pure white, and there is a curious form (listed as bicolor) which bears purple and white flowers on the same bush, often on the same spike. *D. p. globosa alba* is different in habit to the typical plant, being looser in growth and more spreading, while the bells, instead of being elongated and pointed towards the bottom are globular in outline. Crosses between this form and the typical one give plants of similar habit to *globosa* with flowers in pretty shades of lilac and rose.

Of the *Vacciniums*, the Whortleberry (*V. Myrtillus*), is readily naturalised in lime-free soil with a certain amount of leaf-soil incorporated, but it has no special beauty. An American relative, but dwarfer in all its parts—*V. caspitosum*—is useful for rockwork. There is in cultivation a white fruited form of the common Whortleberry. Somewhat like our native fruit, but quite distinct, are the two American species, *V. pennsylvanicum* and *V. canadense*, which do not, however, fruit very freely in Britain. The Cowberry (*V. Vitis-idea*) is a dwarf-growing plant (6ins.) with exceptionally beautiful foliage, rather inconspicuous flowers and deep red berries. The so-called Bog Bilberry (*V. uliginosum*) largely replaces in our Southern Counties the true Whortleberry. It is hardy and worthy of cultivation.

Those giant relatives of the Heaths, the Arbutuses, are often included among "American" plants, though they have no pronounced antipathy to lime. *Arbutus Unedo* is the handsome Strawberry Tree, but the gem of the genus is the gracious Madroño, *Arbutus Menziesii*.

THE JUNE-FLOWERING *LEUCOTHOE DAVISIÆ* HOLDS ITS FLOWER WELL ABOVE THE FOLIAGE.

PLANTING WATER LILIES

Alternative methods described, with their advantages and disadvantages.

THE season has come round when those having ornamental waters may plant the beautiful hardy *Nymphæas* which everyone admires. Before describing the various methods of planting it may be advisable to reiterate what has been said and written so often, namely, that Water Lilies, even the hardiest, will not succeed in cold running water nor where there is considerable shade. Comparatively warm water in summer is necessary for their very existence, and full or almost full sunshine must be available if they are to flower freely. This appreciated, it should further be noted that the new orange-shaded hybrids with more than a touch of less hardy sap in their tissues, and the New World odorata section — so deliciously fragrant—should be accommodated with the warmest, sunniest and most sheltered corners available, leaving the bleaker open waters for our native white Water Lily, *Nymphæa alba*, and for the probably equally hardy *marliacea* hybrids. *N. marliacea carnea* is indeed wonderfully vigorous and free, and *N. m. chromata*, with beautiful mottled foliage, if somewhat smaller in leaf and flower, seems equally hardy and accommodating.

For shallow waters restricted in area the Laydekeri hybrids are most useful, but they lack the vigour and hardihood of the "marliaceas." For specially shallow waters—ft. or even less—and for tiny pools the miniature white *N. pygmaea* and its soft yellow form *N. p. helvola* are invaluable. Both are amazingly free-flowering.

Among so many treasures it might, however, seem invidious to make a selection, so we will pass straight on to methods of planting. The most usual method is probably to sink the rhizomes in flat, round baskets such as nurserymen use for packing trees, etc. A good compost of sound turfy loam with a proportion of decayed cow manure or other source of humus is used to plant the roots in—the rootstocks being buried. The whole is next mossed over, and tarred string, drawn through the baskets below the rim and "criss-crossed," prevents the roots from floating out before they can get established.

Another method often employed is to cut a hole in the centre of a really large turf—as near a yard square as the sod will hold together—to pass the rhizome through and peg the opening together, also pegging a smaller turf to the large one from below with sufficient compost to give the leathery

roots presently to be formed a start in life. This method, since it needs no baskets—which do not always look pretty when seen through clear water—is less expensive, but it must be confessed

that the large turves are not easy to manipulate. A couple of planks if the pool is a small one may be used to slide down the baskets or turves; otherwise, the only alternative to draining is to use a punt.

PRESENT-DAY DAHLIAS, THEIR ORIGIN AND DEVELOPMENT.—I

THE SINGLE-FLOWERED TYPES

FASHIONS in Dahlias do not change as rapidly as Parisian fashions, but they do change and fairly rapidly, too, in these days. For nearly a century after their introduction in 1789 there was but little variation beyond the gradual development of the double or show flower. The acme of Dahlia

of the present day, they gave great impetus to Dahlia cultivation, as many were tired of the formal show type and gladly welcomed the lighter and more elegant single and semi-double forms.

The greatest excitement was caused by the introduction of the Cactus form, which came direct from Mexico, the home of the Dahlia, and was called *Juarezii*, after the President of the Republic. The flower was composed of long, narrow, recurved florets with a close centre, similar in form to a Cactus, hence its name. The colour was brilliant crimson scarlet, and formed a striking contrast to anything yet introduced. *Juarezii* thus became the progenitor of the new class of Cactus blooms, and also exerted considerable influence in the production of other types.

Thus the centenary of the introduction of the Dahlia closed with promising breaks for the future, and since that time we have seen rapid developments in various directions. These are described under their different heads in the following article.

THE SINGLE VARIETALS.

In the single flowers we had at the time of the centenary some good varieties, such as *Paragon*, *Stella Bianca*, *Scarlet Gem*, *Formosa*, etc., and from these progenitors many beautiful varieties were raised which soon became most popular. The smooth recurved florets, even in outline and of most lovely shades of aesthetic colours, with their long wiry stems, make them great favourites for cutting, while in the garden they give a wonderfully brilliant display. One point is of great importance in the cultivation of this section: that is, to take off the seed-pods regularly as soon as the petals drop, and another point is most important in cutting for indoor decoration

which is, to cut the flowers quite young, before they have fully expanded.

A few worth mention as among the best at the present time are *Brilliant*, *Columbine*, *F. Galsworthy*, *Lady Bountiful*, *Marion*, *Miss Roberts*, *Mrs. Johnson Hicks*, *Owen Thomas*, *Rosemary Bridge*, *Snowdrop*, *Wm. Parrot* and *Winona*.

THE COLLARETTES

The *Collaquette*, a form of Continental origin, was quite an innovation. It is perhaps more

DAHLIA WHITE STAR.

bliss was the production of a bloom with a mass of even florets of perfectly globular form, and old-time growers could be seen at the exhibitions bending over their blooms with ivory tweezers correcting the expansion of the florets in order to set up perfect flowers.

Towards the end of the centenary a few innovations were creeping in. There was a return to the early form of single and semi-double flowers. Although these were nothing up to the standard

TYPICAL OF THE STAR VARIETIES,
REIGATE STAR.

THE NEW SEMI-DOUBLE COLLARETTE
VARIETY NOVELTY.

A CHARACTERISTIC EXHIBITION SINGLE,
FRANK GALSWORTHY.

startling than beautiful. The usual form is a single row of outer florets with an inner row of smaller tooth-like florets at the base, contrasting in colour with the outer florets. This quickly took the public eye, and though somewhat wanting in refinement, has been greatly sought after. It certainly is a showy flower, both for garden or house decoration. The following are some of the most useful varieties: Admiral, Bonfire, Colleen, Diadem, Eden, Evangeline, Evelyn, Jean, Juliet, Mrs. Courage, Scarlet Queen and Ustane

THE STAR SORTS.

The latest distinct break has been the introduction of the Star Dahlias. These are so distinct from any others that on their first appearance at the exhibitions they were scarcely recognised as Dahlias. The white variety, with its snow white florets of a cup shape with an orange yellow centre, resembles more closely a Water Lily than a Dahlia. The flowers are rather small, with from two to four rows of petals slightly incurved and pointed, forming a cup-shaped flower with a golden disc. The neat flowers are gracefully posed on long, stiff, wiry stems. They lend themselves wonderfully to light arrangement when cut, in vases, bowls, epergues or baskets. The plants are of medium height, of close habit and wonderfully free in flowering, so that they are practically unsurpassed for either garden display or indoor decoration, and they are now produced in a number of beautiful colours. Some of the best varieties are Autumn Star, Avoca, Coral Star, Crawley Star, Crimson Star, Cuckfield Star, Horley Star, Morning Star, Oriole, Primrose Star, Reigate Star and White Star

NOVELTY.

The latest new form to make its appearance is

the semi-double Collarette named Novelty. This has exactly the form and habit of the Collarette, but instead of a single row of outer florets it has three or four rows, each with the distinct con-

trasting floret at the base. This, as exhibited last autumn, was considered to have promise of something useful.

JOSEPH CHEAL.

(To be continued.)

LUPIN BORDERS

The writer describes how a succession of bloom may be maintained in borders all summer.

IT is sometimes said that the period of bloom of Lupins is so short that they are hardly worth a prominent place in the garden. This is not so, as many of the new hybrids remain in bloom for quite a long period if the spent spikes are cut off. I propose, however, to show how borders can be arranged so as to give

a wealth of blossom from the Lupins, and yet remain attractive when they are over.

The Lupins illustrated are in two long borders, each side a flagged path. The borders are roofed, long and roofed wide. The soil is light and *limy*. We never had any success with Lupins until we tried them in a border where plenty of lime had been applied. Since then we have always given them what they evidently desire, although this is contrary to the opinion of some gardening writers.

Most of our Lupins are self sown and we get a wonderful variety of colour and very strong plants. There are all shades of purple, pink, "mother-o'-pearl" and white. We have one seedling, a hybrid between the tree and herbaceous in growth, with very fine spikes of pale grey and lilac colouring. It reminds one of an old-fashioned lilac print dress.

Behind the Lupins are two rows of Delphiniums, mostly raised from seed, with, here and there, a clump of such fine varieties as Willie O'Brien, Cory, Capri, Belladonna, etc. Behind the Delphiniums are posts and ropes with climbing Roses. In front of the Lupins are Canterbury

REGIMENTS OF LUPINS.

Bells, chiefly pinks and whites, and the beds are edged with that invaluable Catmint, *Nepeta Mussinii*. As soon as the best of the Lupin bloom is over they are cut back and the plants are well mulched. A few of the best spikes are left for seed.

In the course of a week or ten days the Canterbury Bells, Delphiniums and Roses are in full blast and the Lupins are not missed; indeed, the effect at this stage is eminently satisfactory. The photograph was taken last summer, and, because of the awful drought, the plants were not up to their usual standard. Just as the Lupins are going over I dib in Snapdragons wholesale all over the bed. Wherever there is an inch of space in goes a Snapdragon. For this purpose I mostly use the tall varieties and keep to shades of deep crimson, apricot, yellow, orange and white. These are brought on from seed sown early in the year. By the middle of July they are in bloom and blend well with the Roses behind, which consist of Emily Gray, Sander's White, etc. The Snapdragons remain in flower until frosts come.

The Delphiniums are cut right down as soon as they are over, well mulched and watered, and they give us a fair show in September and October. The Lupins also wake up and give a second bloom, but this is not to be compared with their first "shout."

It will be seen by the foregoing that it is a very simple matter to keep two long stretches of borders full of bloom from June until late autumn. These borders are greatly admired by all who see them

MAY-FLOWERING TULIPS IN THE GARDEN

A Word of Praise—Lifting and Storing—Dutch "Breeders"—The Difficulty of Selection—Who can Pick out the Best?—Some Personal Favourites.

THERE is very little doubt that, at the present time, May-flowering Tulips are among the most popular occupants of our gardens. The reasons are not far to seek. We like their bright colours. They flower at a time when, in a sense, they are the monarchs of all they survey. There is nothing just then to compete with them. Lastly, they are so useful for cutting, more particularly the Darwins. The same is true, to a lesser extent, as regards the Cottage section, although here we get some varieties like retroflexa (a pointed flower of soft yellow colouring), Picotee (also pointed, white, edged rose) and La Merveille (a beautiful shade of orange red), which are at the top of the tree for this purpose.

It does not come strictly within the scope of this article, but I cannot pass over without a word of reference the adaptability which nearly all the Darwins and a certain number of the Cottage, such as Inglescombe Pink (buff pink), have comparatively recently been found to possess for growing under glass. I mention it in order that I may warn people who hear of this for the first time against thinking that the same treatment which suits the old-fashioned "earlies," such as Prince of Austria, Cottage Maid and Prince de Ligny, also suits these. Undoubtedly their cultivation under glass is not quite such a simple matter if they are to be had in flower in January or February; but, on the other hand, if April is early enough, there is little difficulty, given the possession of a cold frame and cool greenhouse.

I pass on now to the immediate purpose for which I have taken up my pen, namely, May-flowering Tulips in the garden. It is more than likely that in a good many places they have been used for bedding either by themselves or in combination with other plants, and that the ground is wanted for other things before their foliage has begun to die down. I want to point out that they need not be dug up and thrown away. It cannot be too widely known that if each individual is *carefully* lifted with its leaves and roots as little damaged as possible, and then "heeled in" on some unused bed which is not too much exposed to the heat of the sun, the bulbs may be saved for another year. I know of one large garden where "heeling in" is dispensed with, as the plants are just laid thinly on the ground at the foot of a north wall until the foliage has died down. All the same, I would recommend heeling in if the time and labour involved in the operation are not considered too much.

The question will soon arise as to what is to be done with the bulbs when the foliage has died down. Hands off them until then is the golden rule which should never be broken. If the soil is fairly light, there is no reason why a clump or a bed need be disturbed. The bulbs will have increased to a greater or lesser extent, according to the variety and the suitability of the soil, and when flowers come a second and perchance a third time all that will happen is that there will be a mixture of big and little blooms which for many is as pleasing as the stiffer appearance of a newly planted mass of first-sized bulbs. In stiff soil I advocate annual lifting. Slugs are very fond of Tulip bulbs, and the hollow ways formed from the top of the ground to the bulb by the decayed stems are very convenient high-ways for the hungry or, possibly, the gourmandising slug, and from personal observation I think full use is made of them. Again, if a garden is planted with nice,

THE ROSE-BUD SHAPED TULIP ELLEN WILLMOTT.

THE ROSE, EDGED YELLOW, JOHN RUSKIN.

it should be remembered that mice, too, love a good meal of Tulips; while as for rats, where they are there can at no time be any Tulips. When, many years back, I visited the Scilly Isles, I was told it was impossible to grow Tulips

For this drying stage any airy, but not draughty room or shed where the sun's rays can be excluded may be used. When the bulbs are *perfectly dry*, they may be cleaned, the offsets removed, and the whole of them stored in open trays or on shelves

one side for planting in October or early November; then all that are as large as a hazel nut. These second-sized bulbs should be put in nursery beds not later than the end of September; if in the first or second week of that month, so much the better. The others may as well be thrown away unless they are a very expensive variety. How many varieties there are nowadays!

The latest division is that of Dutch and English Breeders. These have for the most part dark-coloured flowers, and the Dutch are in a very decided majority. Louis XIV, Bronze Queen and Dom Pedro are well known examples. For practical purposes they may be considered to belong to the "Cottages." In fact, many catalogues still make no distinction between them. In no end of things it is difficult to be definite, in none more so than in making a selection of the best. This was very strikingly brought home to me as I stood with Miss Willmott before the splendid exhibit of Mrs. Berkeley of Spetchley's Polyanthus. I began to point out which ones I thought the best. She let me go on for a time, and then said, "Do you know nearly every variety has been picked out by someone or another as the *best*? Ought we to use that word as freely as we do?" I fully appreciate the force of the remark, and yet I think readers expect wretched distracted writers to make selections.

The names that follow are my selection of some of the May-flowering Tulips that I like the best for themselves alone, without considering any garden colour scheme or arrangement or any matching of rooms. I take the Cottage first as being the older section. Long before the late Mr. Krelage introduced the Darwins we had, thanks to the foresight and labour of Mr. William Baylor Hartland of Cork and Mr. Peter Barr of London, a goodly number, which has not grown less with time. Such varieties as Gesneriana spathulata, La Merveille, Orange King and Marksman for red shades; Avis Kennicott, Inglescombe Yellow and Ellea Willmott as yellows; Goudvink, Boadicea and Golden Bronze as bronzy yellows; Inglescombe Pink, Picotee and Mrs. Kerrell as pink and rose and white shades; Dom Pedro and Velvet King for dark shades; and John Ruskin, Faerie Queen and Beauty of Bath as indescribable blends of beautiful soft colouring, with Golden Crown with its yellow petals deeply edged with red, are all, in my way of thinking, extremely beautiful and for the most part of a reasonable price.

As some of my favourite Darwins I would name Farncombe Sanders, Professor Francis Darwin, Pride of Haarlem and Louise de la Vallière for reddish shades; Ronald Gumm, Valentine, Melicette and Euterpe for pale purple or mauve; The Bishop, Moralis, Faust and Jubilee for dark varieties; with Clara Butt, Baronne de la Tonnaye, Flamingo, Suzon, Prince of the Netherlands and Sophrosyne as roses or pinks.

The foregoing selections show the wide range of choice with which May-flowering Tulips provide us. A further question naturally arises as to their disposal in our gardens so as to make the best of them. If the Editor will allow me, I propose to follow up this cultural article with one giving a few general hints about their arrangement.

JOSEPH JACOB.

MAY-FLOWERING TULIPS ARE SPLENDID FOR BEDDING.

"WASHED IN DEW."

there on account of the vast multitudes of these animals which had their homes in the rocky cliffs of the coast.

Let us now suppose the bulbs have been lifted, what must be done then? They should be laid out *thinly* with their roots still attached if these have not already fallen away, but the withered foliage and stems should be pulled or broken off.

if the quantity is large or in paper or cotton bags if the lots are small. It is very important that the storing place be perfectly dry and also mice-proof. I am continually hearing of failures in keeping the bulbs until planting-time from one of these precautions having been neglected. Before then they should be sorted into three sizes. First of all the largest should be picked out and put on

FORTHCOMING EVENTS.

May 23.—Royal Horticultural Society's Chelsea Show (3 days).

SOME OF THE LESSER CAMPANULAS

BY GERTRUDE JEKYLL, V.M.H.

OF the lower-growing Campanulas the one that is of the greatest general utility is *C. carpatica*, for it is large enough to be a useful plant in the front of the flower border and is not too large for the bolder parts of the rock garden. Moreover, it is most accommodating, for it will do well in almost any soil, aspect or situation. The form *turbinata* has flowers of a deeper cup shape, while other garden varieties are more starry; but all are welcome, and when once established give no further trouble; the same plant or group will go on for years, and if a renewed or extended planting is desired it is easily raised from seed. The

colouring is everything between pure white and a fairly deep purple. It is variable as to seedlings, for the produce of a purple plant may give some whites, and that of a white one is likely to throw back to purple.

There are many species of *Campanula* native to the middle European Alps, but among them a few stand out as the most desirable in a garden. *C. muralis*, equally known as *C. Portenschlagiana*, is a brilliant little June flower; the neat tufts of foliage almost covered by the abundant bloom of a rich purple colour. Still more delightful is the dainty little *C. garganica*, flowering later in the summer. There is a perfect finish about the whole plant, with its charming bloom of light

purple shading to white, and its exquisitely neat foliage, like tiny leaves of Ivy, sharply cut at every point. Both of these little Bellflowers are seen at their best in the joints of dry walling, or in any steep places in the rock garden that come near the same conditions. Another of the favourites for wall or rock joint is *C. pusilla*, blooming in late summer. It is in white and purple colourings; a charming pale purple kind was raised by Miss Willmott and is now well known. It is pretty to see any variety of this little plant running at the foot or sides of rock garden steps.

It is well to remember that all these little Bellflowers are happiest in limy soil, a preference that is common to nearly all their kind. Those who have been fortunate enough to have had botanical rambles in Southern Italy will remember the beauty of *C. fragilis* (syn. *Barrelieri*) hanging out of narrow rifts in sheer limestone cliffs. It may not be generally known that this tender plant and the nearly related *C. isophylla*, which in England are usually grown as indoor pot ornaments, may be acclimatised in a sunny wall, where the crown of the plant, set well back between the stones, is protected from winter wet, and where no frost reaches the root. If they are provided with a good compost of lime and loam, or with the natural rich top-soil of chalky places, they thrive amazingly and make larger plants than are usually seen in their native haunts.

There are some species of *Campanula* that are not commonly grown in gardens, but that are well worthy of attention. *C. sarmatica* is a charming plant of late summer, from 1 ft. to 15 ins. high with a profusion of light purple bells and a generally downy appearance. It is good for a place in rough rockwork with a cool exposure. *C. punctata* and *C. nobilis* are plants of rather the same character, both from the Far East—China and Japan. *C. punctata* has drooping, whitish flowers tinged with purple and spotted, and elongated heart-shaped leaves pointed and boldly toothed. These Bellflowers would be lost in the mixed flower border, where plants of a showier nature are wanted; their place is somewhere between garden and wild where a group of either, seen by itself, can be thoroughly enjoyed. I have had them on a raised bank among wild grasses and Ferns, where they flourished and appeared to be just rightly placed.

A CHARMING MINIATURE—CAMPANULA PUSILLA.

THE NOT OVER-COMMON CAMPANULA PUNCTATA.

A FRAGRANT WALL SHRUB

MONGREDFEN, in his excellent book on Trees, states that the lemon-scented Verbena (*Lippia citriodora*) will live out of doors, though sometimes cut to the ground by frost. The scent of the leaves is exquisite. No garden should be without a plant, although it was at one time the fashion to discard it because it has been common. It is said to attain a height of 20 ft. in China.

The only species of this genus known in Britain, it was formerly called variously *Verbena triphylla* and *Aloysia citriodora*. It is a half hardy shrub, with panicles of small pinkish white flowers, and very fragrant leaves, which fall off in the winter. It requires a rich, but light soil, well drained, and when grown in pots it should never have water kept in the saucer. In winter, after it has shed its leaves, it should be kept nearly dry, until the buds begin to swell, when it should be watered frequently and abundantly, but the water should never be suffered to remain in a stagnant state about the roots. It is easily propagated by cuttings and only requires to be protected from severe frosts.

THE SHADING AND VENTILATING OF GREENHOUSES AND FRAMES

In spring and early summer millions of seedlings are raised, plants are repotted and transplanted and young shoots grow freely. In the open air this occurs naturally and in due course; under glass the shoots are forced, are more tender and more liable to be checked and damaged if careful attention is not bestowed upon them.

THE art of applying shade or admitting air to greenhouse and frame occupants lies in the judicious use of shading materials, and the opening of ventilators according to the prevailing state of the weather, not only each day, but every hour of the day. Where, for instance, Vine shoots are young, cold winds prevail and bursts of sunshine are fitful, one must be constantly watching the weather and altering the ventilation of the vinery.

Too much shade spoils the sturdiness of young plants and destroys, or almost destroys, the fruiting powers of such trees as Peaches, Apricots and Vines under glass. Excessive and injudicious ventilation breeds mildew spores and aphides on plants of every kind. We have only to examine closely the undergrowth in our woods to realise all this. It is not only damage that is done in the current year, but it may extend to the following years, too.

The cultivator possesses nice healthy batches of seedlings, it may be of plants intended in due course for filling the beds in the flower garden or for potting on and furnishing the greenhouse. The temperature under glass, in which they are now growing, may be 30° or 40° above the normal outside; if timely shade be not applied, 50 per cent. may be ruined by scorching in an hour's time. Temporary shading will be more beneficial than permanent at this stage, and such shade may be applied by fixing sheets of tissue paper, newspaper, or brown paper, according to requirements, just above the boxes, pots or pans. I usually fix the sheets about 1ft. above the young plants; there is then a free circulation of air around them. When the weather is dull all paper shading material is removed. This method applies, mainly, to plants on shelves or stages in the greenhouse; those in frames are dealt with by placing thin scrim or tiffany or several folds of herring netting on the glass lights, making sure that they are secured against winds.

Where a more permanent shade is required, such may be purchased from firms advertising the various kinds in *THE GARDEN*, and applied according to the instructions given with each packet. Home-made shading material is also very helpful and I know that many amateurs use lime-wash. It should never be used as, when syringed on the glass indiscriminately, the paint on the sash-bars is much damaged by the burning lime; even if carefully applied to the glass only, with the aid of a brush, the rains, in due course, wash some of the lime to the sides and splash it on the woodwork. A mixture of whitening and milk, preferably butter milk, is much more desirable, and this should be applied with the aid of a brush. At this season of the year only the centre portion of the glass between the sash-bars need be coloured, as a very effective shade results and a really liberal amount of unobstructed light reaches the plants.

Then there are roller blinds, of lath, scrim or canvas, which, when properly fixed, are very beneficial to the plants. I think it is a great pity that such rollers should be let down and pulled up daily—probably several times each day—on the painted woodwork of the house, as so much paint is rubbed off. The better plan is to have the rollers running on slightly-raised light iron rods, with a curved end at the bottom to retain the roller.

For Ferns and Palms a permanent green shade is best for the summer months. Fruit trees under glass, with the exception of Muscat Grapes while the stones are hardening in the berries, should not be shaded and then only when the sun is bright; a herring net will be sufficient.

VENTILATION.—This is a very important part of the work to be done daily by amateur or professional. Where owners must be away all day and there is no one to attend to the ventilation of greenhouse or frame in the daytime, it is better to err on the safe side and open the ventilators judiciously in the morning, even if the weather is dull, rather than to run the risk of having healthy plants scorched. Now, we will deal with the proper method of applying air to glass structures, when this can be done at the will of the cultivator. Let us, for the moment, take a vinery as typical of fruit houses. By seven o'clock "summer time" the top ventilators should be opened in, thus a gentle circulation of air is assured and excessive moisture on leaves and bunches is dispersed and scorching does not occur. On a normal day, as the sun gains power, open the ventilators another inch by nine o'clock, and again to gins. wide by eleven o'clock. This applies to the early stages of the growth of the vines; later, as midsummer approaches, more ventilation will be needed, and when the colouring of all fruits begins, front ventilation must also be given and the top ventilator left open in. all night. Where it is convenient all ventilators should be opened opposite to the direction from which the wind blows; till midsummer day this is a very important point.

The necessary air should always be so admitted as not to allow cold draughts to blow directly on to young leaves and fruit.

Cold greenhouses may be more liberally ventilated during the summer, both in the daytime and through the night.

The ventilation of a plant structure should never be put off until the internal temperature is very high. Nor if it has been done should the ventilators then be opened over-wide. Where this is done, plants are chilled, their growth is checked and mildew and aphides result. Open the lights a little first, and early, and begin to close them again gradually also, about one hour before sunset as a general rule.

GEORGE GARNER.

FLOWERING SHRUBS FOR CHALK SOIL

[IN ANSWER TO A CORRESPONDENT]

AS your correspondent "H. E.," page 167, gives no idea of his locality or the area at his disposal, shrubs other than inexpensive and hardy I do not propose to name. Rather vague, too, I think, is the soil description. If I interpret correctly, Rhododendrons and plants similarly fastidious where chalk is concerned would be a doubtful success. Yet soil overlying chalk after years of cultivation contains but a very small percentage of the latter, and may then be tolerated by several species to which anything related to lime is as poison; always providing the

beds to be occupied are raised above the ordinary level to prevent water draining through them from the immediate surroundings. The following selection of shrubs were nearly all planted on virgin soil overlying chalk on the borders of Derbyshire. The site lies low, and is protected on all sides from wind, therefore many somewhat tender sorts flourish, although the district is recognised as excessively cold. It may perhaps be of some help to your correspondent if I group them in order of flowering. Efforts to have something attractive before the advent of April led to the successful planting of *Lonicera fragrantissima* in a sheltered corner. It is a bush Honeysuckle with clusters of small white deliciously scented flowers, and averages about 6ft. in height. *Prunus Davidiana* gives the first Almond blossom. There are two varieties, red and white, but the latter is the freest, and should be so planted as to have the backing of an evergreen shrub, both for shelter and clear effect. *Garrya elliptica* occupies the centre of a most sheltered bed, and is very striking in winter when covered with drooping catkins. Its appearance, however, does not indicate that it will reach in this district a height and breadth of over 12ft., dimensions it frequently attains in the favoured parts of Scotland. Of the Witch Hazel family, *Hamamelis arborea* is sure to please when its leafless branches are freely clothed with what may be likened unto strips of golden yellow. I have known these flowers to come uninjured through 10° of frost. There are several *Viburnums*, but for the period under review *V. Tinus lucidum*, with flower trusses of snowy whiteness and growing about 6ft., is noteworthy. The *Mezereon*, *Daphne Mezereum*, is too common to need but passing mention, yet what shrubby foreground is complete without it and its perfume?

With April, in an average spring, it is not difficult even for the uninitiated to become interested in shrubs. *Magnolia stellata*, 4ft., makes a dense bush, and the profusion of waxy white flowers which open before the leaves are fully developed turns the whole, from a distant view, into a bank of snow. *M. conspicua*, 15ft. to 20ft., blooms later, but the planter must have patience with it, for it is a slow grower, but lovely when at its best. In that delightful Broom, *Cytisus praecox* we have one of our freest-flowering plants, although the month is generally well advanced before the rich primrose-coloured flowers are at their best. Of graceful habit, it does not grow above 5ft., and, unlike some members of the family, does not get leggy. Several of the older Barberries are satisfactory. *B. stenophylla*, *B. Darwinii* and *B. Thunbergii* are all early bloomers. The two first named have yellow, the latter has buff-coloured flowers and is also rich in autumn tints. Here *B. Thunbergii* occupies a position in the front of *Forsythia suspensa*, another yellow-flowered shrub of some merit. Further behind is a bold group of *Prunus pissardii*, planted more for its reddish purple autumn foliage than spring blossom. The latter purpose is left to *Prunus triloba* fl.-pl., grown in standard form and notable for its double rich pink flowers. *Pyrus Malus Scheideckeri* is also freely used as a standard, as is also the Weeping Apple, *Pyrus Malus pendula* Elise Rathke. Both are fascinating when in full blossom. *Cydonia japonica* (Japanese Quince) we used to grow on a wall, but this is an abuse of an ideal comparatively dwarf shrub. *Amelanchier canadensis* is a member of a genus closely allied to the Medlar. The popular title of Snowy Mespilus is an accurate description of it when in bloom, for the effect is nearly snow-like. The foliage, too, is pretty in autumn.

This brings us to the month of May and the flowering Cherries. To produce the desired effect

these require massing, and both bush and standard trained specimens should be used. One of the best is *Trunus Pseudo-Cerasus* James H. Veitch, with large rosy pink blossoms and reddish bronze foliage in autumn. *C. sinensis* Mount Fuji, single white, is also pretty. *Cytisus scoparius* Andreanus, with yellow and violet bronze flowers, is perhaps the handsomest of all Brooms, and it is more profuse in flowering even in a young state. In *Viburnum Carlesii*, 4ft., we find a spring-flowering shrub of much charm. The large flowers are scented, and the colour white, flushed pink. Very often the shrub is at its best before the more robust and better known Guelder Rose, *V. c. pulus sterile*. The Syringas (Lilacs) are, of course freely used, as bushes as well as standards. In some of the newer varieties there is a great improvement noticeable both in habit, colour and size of bloom truss. Especially pleasing are the varieties Alphonse Lavallée, double, blue, shaded violet; Mme. Abel Chatenay, double white; Gloire de Moulins, rose, changing to lavender blue; and Souvenir de L. Spath, the nearest approach to a red.

In June the best of the Deutzias are showy. One of the advantages of their use is due to the neatness of habit, which they retain for many years without interfering with the flowering. In addition to the white *D. gracilis* (largely used for forcing), *D. Lemoinei* (also a white), *D. Boule Rose* and *D. carminea* should be noted. For the hybrid Mock Oranges (*Philadelphus*) no praise is too high. *P. coronarius* is the common species, suitable only for the background of large areas. The following hybrids, however, are dwarf growers and suitable for beds. The blossoms are remarkably fine, and the scent of the type remains. Most of them are descendants of crossing the species named, and *P. microphyllus*, a neat bush 3ft. high with lovely sprays of Quince-scented blossoms, and are grouped under the title of the first raised, namely, *P. hybridus Lemoinei*. So free flowering is the variety *Avalanche* that the branches are often bent down with the weight of bloom. *Candelabra* is nearly as free, but dwarfier in habit; *Boule Rose*, *Gerbe de Neige* and *Mont Blanc* are also splendid. *Spiraea arguta* is seldom good here until June, but it is one of the most beautiful shrubs in cultivation when the branches are clothed with compact clusters of pure white flowers.

For July and August the number of attractive shrubs grows less. *Olearia Haastii*, with dusky white clusters and evergreen, requires a fair amount of space. *Spiraea Anthony Waterer* we employ as an edging, and very pretty indeed it is when the crimson heads of bloom are fully open. *S. arifolia*, with plume-like tufts of creamy white flowers, occupies a moist corner to great advantage. *Hypericum Hookerianum*, 5ft., with drooping waxy golden flowers 2ins. across, is too good to leave out. *H. patulum*, 2ft. is another for the edges. Others for the same period include *Ligustrum japonicum* (6ft.), white; *Cytisus nigricans* (3ft.), yellow; and *Tamarix hispida aestivalis*, with feathery sprays of carmine pink. These notes have extended much beyond my intention when I began, and no mention has been made of new kinds or doubtful doers. But to lay the foundation of a labour-saving plan and a pleasing one, especially if some of the more robust perennial plants are included, as was done here, the foregoing are, I should say, to be relied upon in almost any district. This is a good neighbourhood to test hardihood.—J. T.

CORRESPONDENCE

THE ROTATION OF CROPS.

THERE is, no doubt, a great deal of truth in the advisability of carrying out a system of rotation of crops in the garden, as advocated by "R. D." on page 193. For instance, the sowing or planting of a deep-rooting crop after a shallow-rooting one enables the plants to feed at different levels in the soil, and to draw nourishment from the upper and lower spits in different years. Rotation also helps to check the rapid multiplication of plant enemies, whether insects or fungi. All good farmers certainly practise rotation on the farm. It is not always so rigidly carried out in gardens, especially where on private estates the gardener has a good command of

to grow this crop quite satisfactorily is to make a special bed and grow the bulbs there each year. In the same way many farmers "out for" big roots grow their Mangolds on the same acreage year by year, but such crops may be considered the exceptions which "prove the rule."—ED.

THE ANNUAL STATICES.

THE enclosed photograph of annual Statice may be of interest, particularly to those of your readers who like Everlastings. The plants from which the blossom was gathered were grown in the open border, though raised under glass in a box. The border was fully exposed to the scorching suns of last year, but at planting-time stones were introduced, which these plants undoubtedly like, probably because of the moisture they retain. I have found that rather poor soil suits these annuals better than over-rich compost. The species are *Statice sinuata* (in blue and white and *S. Bonduelli*, yellow.—E. M. L.

IRIS RETICULATA IN POTS.

IT is quite likely that many who know this charming Iris out of doors have never tried to grow it in pots. It cannot be too widely known that if it can be given cool treatment from the time the bulbs are potted until the flowering stage is reached no pot plants are more satisfactory. Potted in September in dwarf flower-pots or low pans and kept as cool as possible they will bloom about the end of January. A greenhouse is not necessary. I have seen beauties which had been grown from start to finish in a cottage parlour window where there was only very occasionally a fire. *Reticulata* is such an early bloomer out of doors that frequently the flowers are injured by inclement weather, especially in the colder parts of Britain. This is avoided by pot culture, as we then get the rich purple blooms with their orange splashed falls in all their beauty and, what must always be an additional attraction, we are able all the better to enjoy their violet-like scent. Seven bulbs in a 5½ in. pan give a good display. Pans or low flower-pots give a better appearance than ordinary pots.—SALOPIAN.

THE PROPAGATION OF MINT.

I WOULD like, if I may, to supplement the excellent article by "H. G." page 180, on the propagation of Mint. I grow quite a number of species and hybrids. One of the latter between the Apple-scented Mint and Spearmint has become a favourite in the kitchen on account of its broad, crisp and juicy leaves. It is later in coming into growth in spring than Spearmint, but makes amends for this by continuing in a fresh and vigorous condition till quite late in the autumn, especially if the flower-spikes are removed. The stems then produce vigorous branches. Of course, Spearmint is the orthodox one for the kitchen. This I have propagated by division and by cuttings from various sources in my endeavour to find if there were any varieties among it, for the Mint usually or frequently on sale in the greengrocers' shops has very narrow leaves, and often withered ones on the lower part of the stems. This I proved to be due to poor cultivation or no cultivation at all in old and neglected beds. I have even obtained forced Mint from the shops and dibbled the cuttings

VASES OF ANNUAL STATICE.

the manure heap. In some gardens, however, certain borders or pieces of ground are set apart for particular crops, whether flowers or vegetables. I know of more than one garden where a certain border was set apart for the Dahlias every year, and nothing appeared lacking in their growth. A nurseryman acquaintance of mine always grew his Dahlias on the same piece of ground, and he was both a raiser and successful exhibitor. I have grown Onions for three years in succession on the same border where they had been grown for twenty years previously, and the crops were heavy. Possibly others will recall that hundreds of small gardens are cropped chiefly or solely with Potatoes year after year.—J. F.

(Despite the ravages of the Onion fly, it is certainly true that on some soils the only way

into the open ground without any protection whatever, and although put in at a foot apart each way, the bed was quite full before autumn. Besides getting vigorous plants from cuttings, it is also a means of getting rid of the Mint rust (*Puccinia Menthae*), which is liable to become serious in neglected Mint-beds.—HORTULANUS.

HISTORY OF THE MOSS ROSE.

MANY readers of THE GARDEN are lovers of the Rose, and many doubtless read "The Rose Annual." In that for 1922 Major Hurst contributes some "Notes on the History of the Moss Rose." In these, on page 40, he says that "the earliest date recorded for the Moss Rose is in a rare little book entitled 'L'Ecole du Jardinier fleuriste.'" I have this work because the frontispiece is so extremely interesting to me as a lover of the Tulip. On it is depicted an *Auricula* stage and, as far as I know, the earliest picture of a covered Tulip-bed. The edition in my possession is dated 1746, which is the identical one from which Major Hurst quotes, but I cannot find any reference in it to the Moss Rose. Either his eyes are better than mine or he is the possessor of a Grangerised copy which contains matter which mine does not. Hence I ask, was there, as Major Hurst states, a Moss Rose in 1696?—J. J.

SOME BEAUTIFUL FLOWERING PLANTS.

I HAD the pleasure of seeing the fine form of *Clematis Armandi* in flower at La Mortola in March which was mentioned in THE GARDEN last year. There was an illustration also given at the same time, but not of the La Mortola plant, and it was stated that there was no botanical difference between it and the plant figured. For garden purposes the difference is *extreme*. The plant figured resembled the form I flowered and threw away as worthless, and much inferior to the New Zealand *Clematis indivisa*, whereas the La Mortola plant is a much bigger and stronger-growing thing with long, narrow trifoliate leaves of great thickness of texture on red-brown shoots of extraordinary vigour and length, while the big bouquets of creamy white, strongly scented flowers were double the size of the variety given in the illustration, so I hope another year THE GARDEN may give a figure of this fine climber, though I think its vigour is such that it is more fit for outdoor culture than under glass. I have been much pleased with the early flowering Lilac Lamartine.

It is so elegant, so early and so vigorous and flowering that it has quite won my favour. It has the great merit of lasting well when cut and in water. It is also very fragrant and true lilac in colour. Looking over bulb catalogues last autumn I came across the name *Tulipa persica* and sent for bulbs as I did not feel to know it. Perhaps other folk may be as ignorant as I, so I will say for their benefit what a pretty little starry flower it is. Growing in bouquets of three or four flowers like *Tulipa saxatilis*, it has flowered in the grass in time to contrast with the latest blooms of the wild *Anemones* of the starry or *hortensis* type, and it seems so thoroughly at home with them I quite expect it will establish itself as *T. saxatilis* does in this climate, and would be equally delightful in rock gardens. The fine red *Glaudiolus* sent out by Van Tubergen as a very early-flowering and upright variety has also been much admired this spring, as the bulbs I got two years ago are earlier the second year than the first. There are so many beautiful bulbs and flowers in beauty here at this season that one can hardly say it is indispensable, but it is nevertheless a fine addition to spring flowers, and is good for table decoration just before the

Roses arrive in quantity. How wonderful these are this spring on this coast after their long enforced rest from heat and drought! I regret to say, however, that the striking climbing Rose Mermaid refuses to bloom with its close allies *Anemone* and *Chinensis*, which is most disappointing, as its clear lemon yellow blooms would have contrasted so well with the rose and the pure white of the two older varieties now in the height of their beauty. The flower-buds of Mermaid are only just beginning to show! I must not forget to mention the great beauty of the hybrid Daisy Miss de Witte, which is a cross between *Agathaea coelestis* and *Felicia petiolata*. Partaking happily of the climbing power of *Felicia petiolata* and the pretty grey blue of the *Agathaea*, it can be used not only to make cushions of flower on rockwork, but can be trained up a post or a tree trunk, and the astonishment of new-comers to this coast when they see a climbing Daisy in full flower at a height of 7ft. or 8ft. is quite an amusement to those who have grown it. [Here would seem to be a welcome addition to greenhouse climbers.—Ed.] That most beautiful evergreen shrub *Sophora secundiflora* is also now at the height of its beauty, and well deserves its name of the evergreen *Wistaria*. It is a great pity that so lovely a shrub is so slow in growth when young and demands a hot, dry summer, but where it succeeds it must be classed among the most beautiful of evergreen shrubs. This coast has not really suffered from the comparative cold of the month of April, but the drought is serious, as there seems little chance of abundant rain this spring, and the outlook is not pleasant to those who garden.—E. H. WOODALL, *Nice*.

AUBRIETIAS FROM SEED.

IN the leading article "Colour in the Rock Garden" (April 22, page 185) mention is made that "to select the best varieties of *Aubrieta deltoidea* is not easy." For some few years I have sown a packet of the best quality of hybrid *Aubrieta* procurable. So far the results have been so perfectly satisfactory that a further sowing will be made about the middle of May. I simply scatter the seed upon prepared ground free from manure just as one does any annual. In about three weeks, if the seed is fresh, the seedlings will make their appearance, and in a very short time will be ready for transplanting. This should be done the moment the tiny plants are large enough to handle, and if possible they are best transferred to their permanent quarters. Under no circumstances should the seedlings become crowded, the object being to promote rapid and vigorous growth. The plants should attain full flowering size in twelve months' time, and in a couple of years form cascades of bloom. The mixed colours I find are very varied and beautiful, ranging from the palest blue to deep purple, rose, carmine to crimson.

From a single packet of seed many different habits of growth may be expected. Some plants will be suitable for covering large spaces, others of a close-growing habit that takes the form of the rockwork. I have one plant of the latter habit that is the first to flower and the last to succumb. Another important point in the raising of *Aubrietias* from seed is the great vigour of the plants, for each have a fresh start in life, and I think that rock plants are more vigorous from seed than when raised from cuttings, etc. We have many other plants raised from seed just by scattering: Hybrid *Columbines*, Forget-me-not, Aster (alpine) *Contranthus*, *Cheiranthus*, *Dianthus*, *Geum*, *Helianthemum*, hybrid *Heuchera* and others. To the amateur gardener tied for time and not in want of large quantities of plants I say, try the raising of these charming plants

from seed. It is inexpensive and effectual. From fresh seed the period of germination is for many kinds only twenty-eight days or so. Caution! do not try any of the Gentians by this method!—J. PARKINSON, *Warrington*.

TWO SPECIES OF LACHENALIA.

MANY years ago, when I first "took up" *Lachenalias*, Sir Frederick Moore made the remark that the different varieties seem to have their years. He doubtless intended to include species in his generalisation, but whether he had them in mind or not, experience tells me that not only have Siam, Thibet and Mandalay—three splendid yellow hybrids of my own raising—their good years, but that with species it is the same. Anyhow my *pallidas* and *glauca*s have surpassed themselves this spring, and if the heights given in Nicholson's "Dictionary" are correct, have become veritable giants. How very few seem to grow any species, and yet in the two I have mentioned we have two of the sweetest flowers that minister to our sense of smell. They remind me so forcibly of the past—of a small conservatory at my old home wherein pots of the yellow *Cytisus* had a prominent place.

These have given me a sort of standard of sweetness, and somehow or other I frequently find myself judging in a rough way the scent of other flowers by them. *Lachenalia pallida*, to me, smells very much like the old market *Cytisus*, and *glauca* is not far off. *Glauca* this year is 14ins. high and *pallida* about 6ins. Their flowers are arranged in spikes in the same way as in the better-known hybrids (e.g., *Nelsonii*), but are either sessile or nearly so. They make no pretensions to great beauty, and just as the milkmaid's face was her fortune ("My face is my fortune, sir, she said"), so with them "Their scent is fortune," for the dull, yellow-looking flowers of *glauca* and the small pale purple flowers of *pallida* are but poor Cinderellas compared with the more conspicuous ones of their hybrid rivals. I fear neither the one nor the other is easy to procure. There has been no demand for them, so but few dealers grow them. Those who can appreciate quiet beauty and who delight in sweet smells will, however, like to grow them. They can be grown to perfection in a cool, airy house.—J. J.

EDITOR'S TABLE

SOME BEAUTIFUL NARCISSI.

THE Editor has received from Messrs. J. R. Pearson and Sons of Lowdham a box of very beautiful Daffodils cut from the open ground, including a blossom of the huge golden trumpet *Le Printemps*, which Messrs. Pearson state had been expanded three weeks. Even after the journey this flower was still in fairly good condition, so that its lasting properties are beyond question. All the sorts sent were of exceptional beauty, but two which especially appealed to the Editor were Lowdham Beauty, a magnificent and substantial white *Leedsii* which, except for the rather foreshortened but widely expanded cup might be taken for a white trumpet variety, and Nora Pearson, a beautiful bicolor Daffodil with a substantial but incurving perianth. Other beautiful sorts were the Giant *Leedsii* Empire; Marshlight, a brilliantly coloured *Barrii* with starry perianth and scarlet cup; the excellent *Incomparabilis* Pedestal, with flat, creamy perianth and long, widely expanded golden cup. *Scarletta*,

a medium-sized Barri of starry appearance, its perianth cream and the compact cup a brilliant deep orange; Sanctity and Vega, both white trumpets of moderate size; Waterwitch, a very

coy self-coloured paper-white Leedsii; and Florence Pearson, a substantial trumpet Daffodil with soft citron yellow trumpet and paper-white perianth.

Spray with Abol Insecticide or Quassia, so that this pest may be kept in check.

Roses.—Look over the Rose beds and free the plants from any Briar suckers that may be showing. Keep the hoe going so that the surface soil may be kept open and clear of weeds.

East Lothian Stocks enjoy a lengthy season of growth so, provided they were sown early, the plants should now be of good size and sufficiently hardened off to allow of their being planted out. This plant thrives best in a rich, retentive soil.

Gladioli.—Named varieties which have been started in pots should now be planted out. If planting in the mixed border and the natural soil is clayey or impoverished, a good spadeful should be taken out and some specially prepared material given to each clump.

Hollyhocks.—Where these attractive plants are treated as biennials they should now be transferred from the nursery border to their flowering quarters. To obtain the finest results Hollyhocks should be given generous treatment. Deep digging and liberal manuring is essential, so that vigorous, disease-resisting plants may be ensured.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Runner Beans.—Whether a small early sowing was risked or not as advised in calendar for mid-April, a sowing should be made now without delay. It is a good practice to make a shallow trench for growing this crop, varying its width to accommodate either a single or double row of plants, whichever is preferred. A rich soil must be provided for this vegetable, and the plants, when finally established, be allowed at least 1ft. of space from each other. Plants growing in boxes or pots must be carefully hardened off before they are set out.

French Beans.—Make sure of a good succession by making another sowing, still choosing for preference a warm, protected position. As with the Runner Bean, they may also be grown in shallow trenches, in which position much cold wind is warded off and protection is more easily afforded if necessary.

Broad Beans.—Should the demand necessitate a further sowing, it is essential that the site chosen be a cool one, and the soil fairly strong as well as rich.

Early Celery.—As soon as the earliest raised plants are large enough they may be placed in their permanent positions. Whether best grown in single, double, or even treble rows is purely a matter of opinion and convenience. The main point is to make sure that the ground has been well prepared and that the plants are well watered in and further copious waterings provided during dry weather.

Later Celery.—Plants should be pricked out as required and kept at all times uniformly moist. A further pinch of seed to provide late plants for use next April should be sown now in a few inches of light soil in a cold frame.

Maize.—Where the cobs of this vegetable are appreciated for autumn use sow the seeds now either singly in small pots under glass to plant out later or directly in their fruiting quarters. The lines require to be about 3ft. apart and the plants 14ins. to 18ins. from each other in the rows. A rich soil must be provided to enable the cobs to develop to their fullest capacity. A row of this vegetable behind an edging of Parsley gives a border a much neater finish than many vegetables.

The Flower Garden.

Water Lilies.—As a general rule, varying according to the season, the present time is as good as any for the planting, or it may be replanting after division of the roots of these pond and lake beauties. There is an article on this subject in this issue, page 22.

Grass Seed recently sown and now germinated should receive several good rollings, which will prove of immense advantage to the young plants. A free use of the roller is also good for those parts of the grounds allotted to tennis, croquet, etc.

Seeds of Sweet Williams, Wallflowers, Canterbury Bells and other biennials generally associated with spring and early summer display should be sown now. It will prove of benefit probably to sow somewhat thinly, so that in the event of a rather long stay in their seed quarters owing to pressure of other work, the young plants will not become too weakly.

Fruits Under Glass.

Old Vines.—The key to success in the management of these is to be as consistently natural in the method of culture as possible. It is a mistake to have any hard and fast rules laid down in respect to temperatures and stopping similar to those often adopted with Vines in full vigour. Fire heat should only be used in moderation, and the plants should be allowed to swell up their buds practically unaided by artificial heat. If the two greatest enemies to successful Vine culture had to be named, they would unquestionably be root dryness and overcropping, and it pays to be doubly careful to try to avoid these errors of management in dealing with old Vines. While disbudding and regulating of the shoots are equally as necessary as with younger Vines, it will be found of benefit if a somewhat greater freedom of leafage be allowed, thus

tending to keep root action in a healthy way, without which no one can grow good Grapes. This ample covering with leafage is particularly applicable to Vines carrying black Grapes, and while it is not advisable to allow shoots carrying bunches to grow too freely, much may be accomplished towards providing a good cover by encouraging the barren shoots to furnish such.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Salads.—To ensure fresh supplies of Mustard and Cress weekly sowings should now be made. A partly shaded portion of the garden suits this delectable salad best as too much exposure to the sun causes toughness in the leaf. See that regular sowings of Radishes are also made, both of the Turnip-rooted and long-rooted types. Lettuce should also be sown in quantity, and early lots thinned out to 8ins. apart. Quantities may also be transplanted to frames that are now cleared of bedding plants. Sutton's Favourite and Webb's Wonderful are splendid sorts for general use. London White and Kingsholm are two of the most useful Cos varieties.

Cauliflowers.—Plant out for succession those that have been raised in frames for this purpose, allowing 2ft. between the rows for the stronger-growing sorts.

Kohl Rabi.—Although this Turnip-rooted Cabbage is not much grown in Northern gardens, yet in certain districts it finds favour, more especially where difficulty is found in growing Turnips, as the roots of Kohl Rabi prove a useful substitute. Sow now and transplant in July in a similar manner to Cabbage.

Dwarf Beans.—Risk a few lines of Canadian Wonder or Sutton's Evergreen on a warm and sunny border for a first crop in the open. The principal sowing should not be made until the end of the month or the first week in June. Sow in rows 18ins. apart and thin freely to 8ins. in the row. Overcrowding should be guarded against as this hinders the full development of the plant, with resultant loss of crop.

Peas.—Attend to the staking of early Peas and make further sowings of Maincrop Marrowfat.

Cucumbers will now be making rapid growth and should receive frequent attention. Stop the main growths and thin out unnecessary laterals, thus allowing more sun and air about the plants. Top-dress where required and feed liberally, both with liquid and artificial manure, plants that are bearing heavy crops.

Fruit Under Glass.

Strawberries.—The latest batch of Strawberries for forcing may now be transferred from the cold frame to the forcing house. Syringe the plants freely morning and afternoon so that red spider may be kept in check. Do not allow the plants to become dry at the roots and assist with suitable stimulants batches that are swelling their fruits.

Peaches.—In the second Peach house the fruit will now be stoning, so it is essential that too high a temperature should not be kept up, either by day or night, as the fruits are particularly sensitive at this time. Tie in the necessary growths for keeping the trees furnished. Continue to disbud in the late house, and thin judiciously before the fruits become too large.

The Flower Garden.

Herbaceous Borders.—Many plants in the hardy border will now require staking and tying, so should be attended to before the growths fall over. Tie the plants in as natural a manner as possible.

Border Carnations.—Searify the soil between the plants and dust the surface with soot or lime, should slugs prove troublesome.

Border Chrysanthemums.—These should now be hardened off preparatory to planting out. Lift the sashes off entirely when the weather is fine and keep a watchful eye on young plants that may be affected by the leaf-mining maggot.

CONSERVATORY AND GREENHOUSE.

Eustoma Russellianum.—This beautiful plant is easily raised from seed, which may be sown at this time, but its subsequent cultivation is by no means easy; in fact, there are few plants that so severely test the skill of the expert cultivator, but when successfully grown and flowered it is well worth all the trouble one can take with it. In common with many plants belonging to the Natural Order Gentianeae there seems some particular difficulty in the cultivation of this plant; this probably due to lack of other plant association. The fine seeds should be sown on the surface and just covered with a dusting of sand. The compost should have a little peat added to it. Stand the seed pots in a cool house and cover with a piece of glass until they germinate. When fit to handle prick off into pans of light soil, and, as large enough, pot in thumbs, watering carefully at all times. The chief aim the first season should be to secure a nice healthy rosette of leaves before winter. Next season pot on as they require it until they are in their flowering pots, which may be 5ins. in size; over-potting should be avoided at all times. Cool-house treatment suits them during all stages of their cultivation; in fact, during their second year they may be grown in cold frames.

Chironia linoides, at one time a popular plant in gardens, is now seldom seen. It is an excellent and beautiful plant for the cool greenhouse, especially so as it flowers during August and September, always a difficult time in the conservatory and greenhouse. The plant is seen at its best during its second year, and plants propagated last year should now be ready for their flowering pots, which should be 5ins. or 6ins. in size. This plant does best in a light, rich compost with the addition of a little good fibrous peat, and by frequent pinching it makes neat, bushy specimens. Cuttings root readily in a close case in a cool house and may be inserted now for next year's stock. Other good species are *C. floribunda* and *C. baccifera*, the latter species being very ornamental when in fruit, the small red berry-like fruits remaining on the plants for a long time. The flowers of all the species mentioned are of a pleasing shade of reddish pink.

Crassula falcata is another useful plant for flowering during August and September, and looks pretty when grouped with well-grown plants of the variegated *Abutilon Savitzi*. The successful cultivation of the *Crassula* presents few difficulties, but it is essential that it have full exposure to sun and light at all times. Other species of *Crassula* that have for many years been favourite garden plants are *C. coccinea*, with sweet-scented, scarlet blooms; this flowers freely in small pots, but can be grown on into large specimens, and at one time was commonly grown as such. *C. jasminea* is a small, neat-growing white-flowering species, at one time a favourite market plant in the London area; hybrids between this species and *C. coccinea* are still grown in quantity for the London market. All the above flower during the summer months, while *C. lactea*, a white-flowered species, flowers during the winter. They all enjoy free drainage, and old mortar rubble and broken bricks may with advantage be added to the potting compost. They all root readily, if kept on the dry side, and fully exposed to light on a shelf in the greenhouse, or even in a cold frame.

Moschosma riparium.—This plant, with its elegant feathery sprays of small white flowers, is very beautiful for winter flowering, especially when grown in the country. In the neighbourhood of London it unfortunately too often gets spoiled by fogs. Cuttings should be inserted towards the end of the month, or even the beginning of June, as it is a quick-growing plant and roots readily in a close case with slight bottom heat. It grows freely in ordinary good potting compost, and only requires an ordinary greenhouse during the growing season.

Coleus thyrsoideus is a beautiful winter-flowering species, with lovely blue flowers, and has the added merit of remaining in flower for a long time. It can be raised from seed, which it produces freely if a few old plants are kept for this purpose, or it may be propagated by cuttings about the same time as advised for the *Moschosma*. It is not, however, by any means such an easy plant to cultivate successfully, for although a strong-growing plant, it requires care in watering at all times. If propagated towards the end of summer, and the small plants are grown on next year, fine large specimens may be obtained during the autumn. The ends of strong shoots may be rooted singly in 3in. pots if placed in a close case; flowered in the same sized pots they are very charming for indoor decoration.

J. COULTS,

Royal Botanic Gardens, Kew.

OBITUARY

S. T. WRIGHT, V.M.H.

We deeply regret to record the death of Mr. S. T. Wright, the popular superintendent of the Royal Horticultural Society's Gardens at Wisley. Mr. Wright succeeded Mr. A. F. Barron as superintendent of the R.H.S. Gardens at Chiswick in 1895, coming from Glewston Court Gardens, Ross-on-Wye, where he had grown hardy fruit and exhibited with great success at most of the large horticultural shows throughout the country. In 1904 the Society moved its gardens from Chiswick to Wisley, and Mr. Wright had charge of the moving arrangements. Here he remained as superintendent until his death, acting also as secretary of the Fruit Committee, and superintending the arrangements of the Temple, Chelsea and Holland House shows.

Endowed with a cheery smile and genial temperament, he will be greatly missed, not only by his colleagues at Wisley and Vincent Square, but by the exhibitors and Fellows of the Society with whom he came in contact. Mr. Wright, who was sixty-three years of age, leaves a widow and several children. For some weeks he had been ill, and at the time of his death he was staying at Matlock, whither he had gone in the hopes of recuperating. In 1920 Mr. Wright had bestowed upon him the Victoria Medal of Honour in Horticulture (V.M.H.). He was a member of the Hortus Lodge of Freemasons. The interment took place on Tuesday, the 3rd inst., at Ashbourne, Derbyshire. There was a memorial service at Wisley on the same day.

Forthcoming Trial of *Salpiglossis*.—The Royal Horticultural Society will carry out a trial of *Salpiglossis* for flowering in spring, 1923, under glass, at their gardens at Wisley. Those desiring to send varieties for trial should post them to the Director (from whom the necessary entry forms can be obtained), R.H.S. Gardens, Wisley, Ripley, Surrey, so as to reach him by May 31, 1922.

A New Flower Show for Lancashire.—It is gratifying to note that the Darwin and District Agricultural Association, which was founded in 1890, has decided to add a Horticultural Section to their Annual Show this year. The show is to be held on Saturday, June 3, and entries close on Wednesday, May 24. Copies of the schedule may be obtained from the Secretary, Mr. R. Leach, 29, Railway Road, Darwin, Lancs.

The Rhododendron Show.—It was erroneously reported in our last issue that an exhibit was staged at the above Show by Mr. Leopold de Rothschild. This should have read Mr. Lionel de Rothschild. Mr. Lionel de Rothschild also received an award of merit for the beautiful new Rhododendron *Aurora*.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.
